THE LEG—With the Colored wool commence at the centre stitch of the front of the boot, and round the ribs formed by the side, worked thus—

1st round—4 chain, miss a rib, 1 plain in the side of the next rib. Repeat all round.

2nd round—Work in the 4 chain, (1 plain, then 3 chain, 1 treble, 3 chain, 1 plain, all in the same 4 chain). Repeat all round, and fasten off.

3rd round—With white wool commence at the top of the 10th rib of the 38 rows, and keeping the little Scallops formed by the last 2 rounds down in the front, work 1 chain, miss a rib, 1 treble in the top of the rib not used in the 1st round. Repeat all round.

4th round—All plain crochet.

5th round—Work in double crochet, that is, putting the needle into both edges of the previous round, and working a plain stitch.

Work 14 rounds more as the last.

20th round—4 chain, miss 1 and 1 plain. Repeat.

21st round—5 chain, miss 4, 1 plain in the 4 chain. Repeat. Join on the colored wool.

22nd and 23rd rounds—Work as the 21st round. Join on the white wool.

24th and 25th rounds—Work as the 21st round.

26th round—1 chain, miss 4, 1 plain in the 5 chain. Repeat, and fasten off.

THE SOLE.

With the Colored wool make a chain of 9 stitches.

1st row—Miss 1, 2 plain in one stitch, 7 plain, turn back.

Now work the rest of the sole in double crochet, which being worked backwards and forwards, will have a different effect from the leg.

2nd row—2 plain in the first stitch, the rest plain. Work 8 rows more the same as the last. There will now be 18 stitches.

11th and 12th rows—Plain.

13th row—Miss 1, the rest plain. Work 5 rows more as the last. Then 4 rows plain.

23rd row—2 plain in one, the rest plain. Work 7 rows more as the last.

31st and 32nd rows—Plain.

33rd row—Miss 1, the rest plain. Work 5 rows more the same.

39th row—Miss 1, the rest plain to the last 2 stitches, then miss 1, 1 plain.

Work 3 rows more the same, and fasten off. Sew the sole to the front, and finish with a bow and ribbon run into the open row at the leg.

LADY'S STOCKING.

IN RIBBED KNITTING.

Materials—5 ounces of Andalusian, Eider, or Welsh Yarn, 5 Knitting Needles No. 18 Bell gauge. The following directions will make a full size stocking, viz., 15 inches round the top of the leg, 26 inches from the top to the heel, and 10½ inches long in the foot. By using Nos. 19 or 17 Needles a size smaller or larger can be made. See Page 13.

Commence at the top of the leg, and to make the foundation strong, the wool should be used double in casting on the stitches. Cast on 42 stitches on each of two needles, and 36 on the other two; keeping the fifth for making it round.

1st round—Pearl 3 stitches and knit 3 stitches plain alternately all round, in all 156 stitches. Continue the same until it is 13 inches in length.

Always pearl or knit the same stitches throughout the leg.

TO SHAPE THE LEG—1st round—Pearl the 3 first stitches; then to decrease, slip 1, knit 1, and turn the slipped stitch over; knit 1 plain; pearl 3 and knit 3, to within 2 stitches of the end, and decrease again by knitting them together.

Knit 8 rounds without decreasing.

Repeat the same, decreasing 2 stitches every 9th round, until it is reduced to 120 stitches.

In these rounds the 3 first stitches are always to be pearled; but the few stitches immediately following will vary, on account of the decreased stitches altering the number to be knitted or pearled. After the decreasing is worked three times, the stitches will require

to be pearled together until the rib is decreased.

When the work is reduced to 120 stitches, sufficient rounds are to be worked without shaping to make it 23 inches in length from the top.

TO FORM THE HEEL—1st row—Knit 1, pearl 1, knit 28; turn back, so as to work on the 30 stitches, leaving the rest of the stitches unworked.

2nd row—Slip 1, pearl 29; then pearl 27 off the next needle; in all 57 stitches; turn back, leaving 63 stitches on the other needles for the Instep.

3rd row—Slip the 1st stitch, knit, 27, pearl 1, knit 28; turn back.

4th row—Slip 1, pearl 56 stitches; turn back. Repeat the 2 last rows 25 times more.

TO ROUND THE HEEL—47th row—Slip 1, knit 21, knit 2 together, knit 8, knit 2 together, knit 1, turn back, leaving 22 stitches on the other needle.

48th row—Slip 1, pearl 12, turn back, leaving 20 stitches—slip 1, knit 2 together, knit 9, knit 2 together, knit 1, turn back; † slip 1, pearl 14—that is, 2 stitches on those left unworked, turn back—slip 1, knit 2 together, knit 11, knit 2 together, knit 1, turn back. Repeat from † 9 times more, always knitting or pearling 2 stitches more each time, so as every row to use two of the stitches left; when finished, there will be 33 stitches.

THE INSTEP—Take another needle and raise 26 stitches from the selvedge formed by the rows of the left side of the Heel; then with a second needle work across the Instep (pearling 3 and knitting 3 as before, 10 times); then pearl 3; and with a third needle raise 26 stitches from the right selvedge of the Heel; and with a fourth needle knit the 33 stitches of the Heel. It will now be 148 stitches round.

1st round—Work across the instep. (Pearl 3 and knit 3, alternately as before, 10 times) then pearl 3; knit 1, knit 2 together, knit 79 plain; then knit 2 together, knit 1 plain.

2nd round—(Pearl 3 and knit 3, 10 times), pearl 3, knit the rest of the round all plain.

Repeat these two rounds 16 times more, knitting two stitches less at the stitches marked in italics each time. Then knit four inches the same as the 2nd round.

THE TOE—1st round—Knit 2 together, knit 49 plain, knit 2 together, knit 4 plain. Repeat once more to finish the round. 2nd round—All plain.

Repeat the last 2 rounds, knitting 2 plain less each time instead of 49, until it is reduced to a few stitches. Then double the work, and knitting a stitch off each needle together, cast them off.

ZOUAVE VESTE.

IN TRICOT ECOSSAIS, WITH TATTING EDGE.—SEE FRONTISPIECE.

Materials—6 ounces of Crimson, Mauve, Grey, or Violet 4-ply fleecy, and Walker’s Tricot Needle No. 4 Bell gauge. For the Border 2 skeins of White Berlin Wool, a large Shuttle, and round mesh No. 1 Bell gauge.

THE BACK.

Commence with 7 chain and work as directed for the Back of the Crossover, page 9, ending with the 4 plain rows.

TO SHAPE THE RIGHT SIDE.

1st row—Continue working from the last row of the back. Raise 28 loops, leaving the rest unworked for the other side. Work Back on these 28 loops.

2nd row—Raise all the loops of the last row to within 3 loops of the end, then to decrease take 2 loops together as one stitch, raise the last loop. Work back.

3rd row—Same as 2nd row.

4th row—Raise all the loops of the last row. Work back to within 4 loops, of the end, keep the 5th loop on the needle, and instead of finishing the row, put the needle into the next stitch to the _left_, and raise a loop so as to commence the next row.

5th row—Continue raising all the stitches of the last row. Work back all the loops on the needle.

6th row—Raise 4 loops, but in raising the 5th loop, put the needle into the next stitch of the lower row, which is under the one ordinarily used. This will prevent any space showing where the last row was turned. Raise the rest of the row as usual. Work back.

7th row—Raise all the loops without shaping. Work back.

Repeat the 4th, 5th, 6th, and 7th rows, 5 times more.

28th row—Raise a loop, increase a loop, then raise all the loops to within 4 loops of the end, decrease by taking 2 loops together, and raise the last two loops. Work back.

29th row—Raise all the loops to within 4 of the end, then decrease, and raise the last two loops. Work back.

Repeat the last two rows 10 times more. Then work 5 rows, leaving 2 loops unworked at the right end of the needle each time; which finishes the right side. The last row is to be attached to the right side of the first 10 rows of the back after the Border is worked.

THE LEFT SIDE.

1st row—Commence at the stitches of the Back, and, leaving 9 stitches for the neck, raise the rest of the row—in all 28 loops. Work back.

2nd and 3rd rows—Work as usual, decreasing at the beginning of each row.

4th row—Raise all the loops to within 4 stitches of the end of the last row, and, leaving them unfinished. Work back.

5th row—Raise all the loops of the last row, then raise the 4 loops of the lower row. Work back.

6th and 7th rows—Work the rows without shaping.

Repeat as the 4th, 5th, 6th, and 7th rows, 5 times more.

28th row—Raise a loop, then decrease. Raise all the loops to within 2 of the end. Increase a loop, and raise the 2 loops. Work back.

29th row—Raise a loop, decrease, then raise all the loops to the end.

Repeat the last two rows 10 times more; then work 5 rows, leaving 2 stitches at the left side of each row, and fasten off. After the Border is worked, sew it to the left side of the back.

THE SASH.

Work as the Lappets of the Hood, page 4, commencing with the same color as the Veste, and using the white wool for the Edge.

Make the Scallop Trimming with the white wool, and for the Joining use the same color as the Veste.

THE BORDER.

For the Outside, commence with the white wool at the last stitch of the left side of the Veste, so as to work on the selvedge formed by the end of the rows, putting the needle sufficiently deep in the work to correspond with the edge row of the Sash: work 3 plain crochet stitches; * then 1 treble in the next stitch, 1 chain, 1 treble, 1 chain, and 1 treble again; these 3 treble stitches are all to be worked in the same stitch of the Veste, then work 7 plain; and repeat again from *, continuing the same all round to the opposite end at the right side of the Veste. As the 3 treble stitches should come at the centre of the back, it will be necessary to increase in rounding the point.

Make sufficient of the Scallop Trimming to go along this row, and join it the same as the Sash. For the inner Border, commence at the last stitch of the right side of the Veste, and work as the outer border. The last row of each of the sides is then to be sewn to the back under the Border, and the Sash ends attached on the wrong side. The Veste should be fastened with buttons down the front.

KNITTED MUFFATEE.

FOR A GENTLEMAN.

Materials—1 ounce of White and 6 skeins of colored Single Berlin Wool; pair of Walker's knitting pins No. 12 Bell gauge. See page 13.

Commence with the Colored wool, and cast on 48 stitches.

1st row—Slip 1, knit 1, then (pearl 2 stitches and knit 2 alternately to the end).

Knit 5 rows more the same.

Join on the white, and knit 6 rows. Then 3 rows of the colored.

For the Centre, knit 36 rows of white—then 3 rows of coloured—6 rows of white, and 6 rows of coloured.

For the Lining, knit 60 rows of white. Cast off. Sew the sides together, then double the cuff and sew the first and last rows together.

ROUND SHETLAND VEIL.

KNITTING.

Materials—One ounce of Shetland Wool and a pair of Knitting Pins No. 14 Bell gauge.

THE CENTRE.—Cast on 49 stitches loosely with two pins.

1st row—Make 1, knit 2 together, * make 1, knit 3 plain, make 1, knit 3 all together. Repeat from * to the last 5 stitches, then make 1, knit 3, make 1, knit 2 plain.

2nd row—Make 1, knit 2 together, * make 1, 2 together, knit 1, 2 together, make 1, knit 1; repeat from *, and at the end knit 2 plain instead of 1.

3rd row—Make 1, knit 2 plain; * make 1, 2 together, make 1, 3 together, make 1, knit 1. Repeat from * to within 5 stitches of the end, then make 1, knit only 2 together, make 1 and knit 3 plain.

4th row—Make 1, 2 together; * make 1, knit 1, make 1, 2 together, knit 1, 2 together. Repeat from * to the last 3 stitches, then make 1, knit 1, make 1, knit 2 plain.

The work will now be increased 6 stitches. Commence again at the 1st row and repeat these four rows until it is the required size; then knit three rows plain and cast off.

Make sufficient of the Diamond Border to edge it.

DIAMOND EDGING.

Commence by casting on 12 stitches.

1st row—Make 1, knit 2 together, knit 1, make 1, knit 2 together, knit the rest plain. The 3rd, 5th, 7th, 9th, 11th, 13th, and 15th rows are all worked as the 1st row, and are therefore not given.

2nd row—Make 1, knit 3, make 1, 2 together, knit 4, make 1, 2 together, knit 1.

4th row—Make 1, knit 5, make 1, 2 together, knit 3, make 1, 2 together, knit 1.

6th row—Make 1, knit 1, 2 together, make 1, knit 1, make 1, knit 1, 2 together, make 1, 2 together, knit 2, make 1, 2 together, knit 1.

8th row—Make 1, knit 1, 2 together, make 1, knit 3 (make 1, 2 together and knit 1, three times).

10th row—Make 1, knit 3 together, knit 1, make 1, 3 together, make 1 knit 1, 2 together, make 1, knit 3, make 1, 2 together, knit 1.

12th row—Make 1, knit 3 together, knit 1, (2 together twice), make 1, knit 4, make 1, 2 together, knit 1.

[Illustration]

14th row—Make 1, knit 3 together, then 2 together, make 1, knit 5, make 1, 2 together, knit 1.

16th row—Make 1, 3 together, make 1, knit 6, make 1, 2 together, knit 1. Commence again at the 1st row. When sufficient is made it is to be sewn to the Veil.

THE “EMPIRE” PETTICOAT.

TRICOT ECOSSAIS.—SEE FRONTISPIECE.

Materials—1lb. of Scarlet or Mauve 4-ply Fleecy; also 2 ounces of Black and 1 ounce of White Wool. Walker’s Tricot Needle No. 5 Bell gauge.

FIRST STRIPE.

Commence with the Scarlet Wool, and make a chain of 33 stitches.

Work 2 rows of Tricot Ecossais as described at page 28, then join on the Black Wool to finish the last stitch.

3rd row—Black—Raise the 1st loop, then increase a loop, raise 13 loops; then decrease by taking 3 loops on the needle and working as one stitch. Raise 13 loops, increase again, and raise the two last loops. Work back. All the rows are worked in this manner, that is, increasing at the beginning and end, and decreasing in the centre.

4th row—Work as the last row.

Then with the White Wool work a row as the last.

Black 2 rows.

Scarlet 10 rows.

18th row—Raise the 1st loop and increase as before. Raise 11 loops, then decrease by taking 2 loops together; decrease again, taking 3 loops together as usual; then decrease a third time, taking 2 together. Raise 11 loops. Increase and raise 2 loops. There will now be only 31 loops. Work back.

Work 10 rows more as the 3rd row, but raising 12 loops instead of 13 on each side of the centre decreased stitches.

29th row—Work as the 18th row, but raising 10 loops instead of 11 loops on each side the decreased stitches.

Continue working 10 rows as the 3rd row, and then a row decreasing 3 times in the same manner as the 18th row, until the work is reduced to 23 stitches, when it will be about 30 inches in length.

As the number of stitches decreases each time the 18th row is worked, a less number of stitches must be raised on each side of the centre.

To finish the Stripe work 3 rows, decreasing in the centre and leaving 2 stitches unworked at each side; then work back to the right side, and end with a row of single crochet.

For an ordinary sized Petticoat 10 stripes will be required. The last stripes should not be joined to the top.

THE EDGE—With the Black Wool commence at the top of the left side of a Stripe, and work down the selvedge a row of plain Crochet, putting the needle into the open spaces formed by the increased stitches. This row should be worked loosely. Continue this row across the foundation, and up the right side of the Stripe. Work the other Stripes the same.

THE JOINING ROW—With the White Wool commence at the black stitch even with the white row of the stripe; work a single stitch on the stripe. Take a second stripe, put the needle into the corresponding stitch of it, work another single stitch. Continue working a

single stitch alternately on each stripe, until they are joined; the needle should be put in both edges of the black row. The first four rows of the stripes are to be sewn together with Scarlet and Black Wool.

THE BORDER—With the White Wool commence at the black row of the foundation, and work a row of 1 chain, miss 1 and 1 plain; putting the needle in the same scarlet stitches as the black row, so as to cover the alternate stitches of it. Repeat all round.

With the Scarlet Wool work 3 chain, miss 1 and 1 plain in each chain stitch of the white row.

TRICOT ECOSSAIS.

A CHAIN ROW is always made for the foundation of the work, the same as in Crochet, and after the number of chain stitches are made, as given in each direction, the last loop is to be kept on the needle.

[Illustration: SECTION.]

1st row—still keeping the loop on the needle—miss the 1st chain stitch, put the needle into the next chain stitch, take up the wool on the needle and draw it through in a loop; * keep the two loops on the needle, put the needle into the next chain stitch and repeat from * to the end of the chain. This is termed “raising” loops or stitches, and there should be as many loops on the needle as the foundation chain.

To “Work back”—Take up the wool on the needle and bring it through the last loop on it, * then take up the wool again and bring it through the two next loops, as shown at the left side of the Section. Repeat from * to the end.

In raising the loops for the 2nd row the needle is to be put into the upright loops of the previous row, as shown in the two first loops at the right side of the section.

To “Increase”—The third loop on the needle is an increased stitch, which is made by putting the needle between two upright loops and bringing the wool through as usual.

In counting the loops always reckon the number on the needle, including the one at the edge.

* * * * *

To insure correctness in the size of the Needles used in Mdlle. Riego’s publications, a drawing of the Gauge by which they are numbered, is now given. All Knitting Needles are measured in the circle close to the numbers. Tricot Needles the same, gauging by the stem.

H. WALKER,

Manufacturer to the Queen of Pins, Fish Hooks, Hooks & Eyes, Hair Pins, Thimbles, &c.

WAREHOUSE—GRESHAM STREET, LONDON, E.C. MANUFACTORY—ALCESTER.

[Illustration: BELL GAUGE]

H. WALKER’S NEEDLES have long enjoyed great popularity with those who value really good Needles. They have been greatly altered by Patented Improvements of a most important character.

H. WALKER’S PATENT PENELOPE CROCHETS have had so many imitations, it is necessary to repeat the request that all who wish for the true Needle will see that the word “Penelope” is on the handle.

The new Patent Uncotopic Handles to the Penelope Needles have the word “Uncotopic” on each, and persons who would avoid disappointment will please to observe these trade marks. The Uncotopic Handle keeps the Needle at all times in the true position for work, and is invaluable alike to a beginner, or to an accomplished worker.

[Illustration: H. Walker Needles

Fig. 1.

Fig. 2.]

The following is from "_The Engineer_," of May 4, 1859:—"Difficult as it may appear to entirely change the structure of so small an article, the figures above show what may be done even with the eye of a Needle.

"Fig. 1. A, is a ridge or slightly raised part before the eye; B, the eye; C, a groove beyond the eye into which the thread falls.

"Fig. 2 is a side view of the part A, B, C, showing the thread recessed as in sewing, when the usual pressure of the thimble drives the Needle with its thread at once through the cloth, affording relief of no ordinary character to the tailor or seampstress, and saving much of their time. We have submitted these Needles to a good judge of such articles, who has declared them superior to all others, not only as above stated, but particularly also with relation to facility of threading."

CHRISTMAS PRESENTS AND NEW YEAR'S GIFTS FOR ALL WHO COURT THE GAY AND FESTIVE SCENES.]

ROWLANDS' MACASSAR OIL,

IS A DELIGHTFULLY FRAGRANT AND TRANSPARENT PREPARATION FOR THE HAIR.

And, as an invigorator and beautifier, beyond all precedent. It bestows a permanent gloss, with a silky softness, and a strong tendency to curl, and is the only known specific capable of effectually sustaining the Hair in decorative charm during the exercise of dancing, or the relaxing effects of crowded rooms. Prices 3s. 6d.; 7s. 10s. 6d.; equal to four small, and double that size, 21s. per bottle.

ROWLANDS' KALYDOR,

FOR THE SKIN AND COMPLEXION.

A balmy, odoriferous, creamy Liquid, as equally celebrated for safety in application as

UNEQUALLED FOR ITS RARE AND INESTIMABLE QUALITIES.

The radiant bloom it imparts to the cheek, the softness and delicacy which it induces of the hands and arms, its capability of soothing irritation, and removing cutaneous defects, discolourations, and all unsightly appearances render it

INDISPENSABLE TO EVERY TOILET.

Price 4s. 6d. and 8s. 8d. per bottle.

ROWLANDS' ODONTO,

OR PEARL DENTIFRICE.

A White Powder, compounded of the choicest and most _recherché_ ingredients of the Oriental Herbal, and of inestimable value in

PRESERVING AND IMPARTING

A PEARL-LIKE WHITENESS TO THE TEETH;

STRENGTHENING THE GUMS; AND IN GIVING A PLEASING FRAGRANCE TO THE BREATH.

Price 2s. 9d. per box.

Sold at 20, Hatton Garden, London, and by Chemists and Perfumers.

The Origin, Tendencies and Principles of Government

Victoria C. Woodhull

Project Gutenberg Release: January 08, 2022 · eBook #67127

[Illustration: _Victoria C Woodhull_]

THE ORIGIN, TENDENCIES AND PRINCIPLES OF GOVERNMENT: OR, A REVIEW OF THE RISE AND FALL OF NATIONS FROM EARLY HISTORIC TIME TO THE PRESENT; WITH SPECIAL CONSIDERATIONS REGARDING THE FUTURE OF THE UNITED STATES AS THE REPRESENTATIVE GOVERNMENT OF THE WORLD AND THE FORM OF ADMINISTRATION WHICH WILL SECURE THIS CONSUMMATION. ALSO, PAPERS ON HUMAN EQUALITY, AS REPRESENTED BY LABOR AND ITS REPRESENTATIVE, MONEY; AND THE MEANING AND SIGNIFICANCE OF LIFE FROM A SCIENTIFIC STANDPOINT, WITH ITS PROPHECIES FOR THE GREAT FUTURE.

BY VICTORIA C. WOODHULL.

NEW YORK: WOODHULL, CLAFLIN & CO., 44 BROAD STREET. 1871.

Entered according to act of Congress, in the year 1871, by VICTORIA C. WOODHULL, in the office of the Librarian of Congress, at Washington.

FROM THE CO-OPERATIVE PRESS, 30 BEEKMAN STREET, NEW YORK.

INTRODUCTORY.

Specializations have been characteristic of the present generation. Branches of science, philosophy or art have been selected and treated as though possessed of great and independent importance. The process of individuality has been the cause; but true evolution, whether in man or matter, consists in viewing whatever is presented for consideration as being related to all the rest, and as a part of the whole.

It will be evident to the careful reader that the various subjects contained in this volume were not originally prepared for this purpose. In several instances the same points receive consideration, which, while they perhaps interfere with the general consecutiveness of the entire work, would interfere still more with the construction of its parts, were they omitted. For this we have no other apology to offer.

Perhaps, however, an explanation is due for errors which have undoubtedly been passed unnoticed. During the publication we have been variously engaged and not able to devote the time actually requisite to reviewing a work of this character. Very much of the proof-reading has necessarily been intrusted to others, and we regret that some typographical errors have crept in. Those we have noticed are so evident they scarcely need be mentioned. In one case evolution has been rendered revolution; in another, evolve, revolve; in another, farce, force, etc. All who might desire to read part of this book may not care for other parts. Those who would find food for thought in “The Basis of Physical Life” might not care to inquire whether the governmental evolution of the world has been consistent and persistent; but we trust that everybody who takes up this book will carefully read “The Limits and Sphere and the Principles of Government,” and “Papers on Labor and Capital and Commerce,” for these immediately concern us all.

In introducing the Constitution of the United States and the late action in reference to human rights, it is hoped to meet in a manner the rapidly-growing demand for information upon the Woman Question, and in giving it the prominence of introducing the book to our readers, we trust to cause further inquiry into the subject of the equality of human rights. Asking the indulgence of an ever generous public we commit our effort to its care, with the hope that the Providence of God may approve it, and that it may benefit that humanity in whose cause I profess to labor.

VICTORIA C. WOODHULL

NEW YORK, February 1, 1871.

GOD IN CREATION, IN HISTORY AND IN GOVERNMENT.

Almighty God! Who art alone first cause, Of all that Nature works through changeless laws, Maker and author of whate’er we see That lives Thy life amid eternity.

Look back ere time was, and the face of earth, Lifeless and still, was solitude and dearth; No lovely valleys and no hills sublime; No rocks or waters marked the hours of time.

Yet look again; behold the grass-clad hills, Dew-spangled, multitudinous with rills, Yet lifeless still: no reason and no sight, That in these many glories know delight.

Yet look again; field-beasts and birds of sky Range woods and glades mere hunger to supply; And time rolls onward, rocks grow old and gray, And Nature’s face is wrinkled with decay.

Yet look again; Creation’s fullness past, And one supreme is born. Man comes at last; Man, who to man is what God is to earth; God’s image in the soul; in form her birth.

Yet look again; Man reaches to his prime, Like God, creating through fixed laws and time, Must he not, too, through each gradation go, Reaching to higher passes from the low?

Is not our life breathed forth from God’s own breath? Once having lived, can we in truth know death? Each soul from birth until the final sleep, Must on God’s own fixed lines its travel keep.

Then, wherefore, with loud prayer and unctuous face, To brother say: “Ye run a foolish race To the abyss.” For how shall any know Whither God’s ministry shall make us go?

Doubt ye the power that governs everything That lovely earth from chaos forth did bring? Canst mark the line where ceases God’s command From work that’s done by man’s own shaping hand?

Forever, no! For man is but effect Of causes which the Father doth direct; Each act and thought and movement of his soul Hath source in God, the Infinite and Whole.

From earthly things man must his body feed; But doth not soul from Heaven its nurture need? His earthly frame bound earthward by fixed laws, Doth not the soul yearn for a heavenly cause?

Brothers to brothers linked, and each to all, Live we one life on this terrestrial ball; One life of those who live and those who die, Of those whom sight knows and whom memory.

Those elder brothers on that farther shore, Risen higher than we in wisdom and in lore, Send messages of knowledge and of love; But know we well that these come from above!

For angels' wisdom to the earth descends, And each fresh hour some bright, fresh wisdom sends; Each day some wonder of new lore displayed, Each year man's mind with triumph new arrayed.

Can mouldering relics, or can fossiled creeds, Provide the quickening age her mighty needs? Can codes, half dead, framed in days long gone by, The soul's new wants, so manifold, supply?

New palaces of Science, Faith and Truth, Tower o'er the humble dwellings of our youth. Shall rule and State, then, in their old ways stand, Denying Progress her supreme demand?

Yet stand they do, and with contemptuous pride, Fling Reason, Progress, Hope and Faith aside. Shall the soul's mighty yearnings thus have end? As well with words think God's own plans to bend.

Decrees are sealed in Heaven's own chancery, Proclaiming universal liberty. Rulers and Kings who will not hear the call, In one dread hour shall thunder-stricken fall.

So moves the growing world with march sublime, Setting new music to the beats of Time; Old things decay, and new things ceaseless spring, And God's own face is seen in everything.

CONSTITUTION OF THE UNITED STATES.

ARTICLE I.

SEC. I.—All legislative powers herein granted shall be vested in a Congress of the United States, which shall consist of a Senate and House of Representatives.

SEC. II.—1. The House of Representatives shall be composed of members chosen every second year, by the people of the several States; and the electors in each State shall have the qualifications requisite for electors of the most numerous branch of the State Legislature.

2. No person shall be a Representative who shall not have attained the age of twenty-five years and been seven years a citizen of the United States, and who shall not, when elected, be an inhabitant of the State in which he shall be chosen.

3. Representatives and direct taxes shall be apportioned among the several States which may be included within this Union, according to their respective numbers, which shall be determined by adding to the whole number of free persons, including those bound to service for a term of years, and excluding Indians, not taxed, three-fifths of all other persons. The actual enumeration shall be made within three years after the first meeting of the Congress of the United States, and within every subsequent term of ten years in such manner as they shall by law direct. The number of Representatives shall not exceed one for every thirty thousand, but each State shall have at least one Representative; and until such enumeration shall be made the State of New Hampshire shall be entitled to choose three; Massachusetts, eight; Rhode Island and Providence Plantations, one; Connecticut, five; New York, six; New Jersey, four; Pennsylvania, eight; Delaware, one; Maryland, six; Virginia, ten; North Carolina, five; South Carolina five, and Georgia, three.

4. When vacancies happen in the representation from any State, the executive authority thereof shall issue writs of election to fill such vacancies.

5. The House of Representatives shall choose their Speaker and other officers, and shall have the sole power of impeachment.

SEC. III.—1. The Senate of the United States shall be composed two Senators from each State, chosen by the Legislature thereof, for six years; and each Senator shall have one vote.

2. Immediately after they shall be assembled in consequence of the first election, they shall be divided, as equally as may be, into three classes. The seats of the Senators of the first class shall be vacated at the expiration of the second year, of the second class

at the expiration of the fourth year, and of the third class at the expiration of the sixth year, that one-third maybe chosen every second year; and, if vacancies occur by resignation or otherwise, during the recess of the Legislature of any State, the Executive thereof may make temporary appointments until the next meeting of the Legislature, which shall then fill such vacancies.

3. No person shall be a Senator who shall not have attained the age of thirty years, and been nine years a citizen of the United States, and who shall not, when elected, be an inhabitant of that State for which he is chosen.

4. The Vice-President of the United States shall be President of the Senate, but shall have no vote unless they be equally divided.

5. The Senate shall choose their other officers and also a President _pro tempore_, in the absence of the Vice-President or when he shall exercise the office of the President of the United States.

6. The Senate shall have the sole power to try all impeachments. When sitting for that purpose they shall be on oath or affirmation. When the President of the United States is tried, the Chief Justice shall preside; and no person shall be convicted without the concurrence of two-thirds of the members present.

7. Judgment in cases of impeachment shall not extend farther than to removal from office, and disqualification to hold and enjoy any office of honor, trust or profit under the United States; but the party convicted shall, nevertheless, be liable and subject to indictment, trial, judgment and punishment according to law.

SEC. IV.—1. The times, places and manner of holding elections for Senators and Representatives shall be prescribed in each State, by the Legislature thereof; but the Congress may, at any time, by law, make or alter such regulation, except as to the places of choosing Senators.

2. The Congress shall assemble at least once in every year; and such meeting shall be on the first Monday in December, unless they shall by law appoint a different day.

SEC. V.—1. Each House shall be judge of the elections, returns and qualifications of its own members; and a majority of each shall constitute a quorum to do business, but a smaller number may adjourn from day to day, and may be authorized to compel the attendance of absent members, in such manner and under such penalties as each House may provide.

2. Each House may determine the rules of its proceedings, punish its members for disorderly behavior, and, with the concurrence of two-thirds, expel a member.

3. Each House shall keep a journal of its proceedings, and from time to time publish the same, excepting such parts as may, in their judgment, require secrecy; and the yeas and nays of the members of either House on any question, shall, at the desire of one-fifth of those present, be entered on the journal.

4. Neither House, during the session of Congress, shall, without the consent of the other, adjourn for more than three days, nor to any place than that in which the two Houses shall be sitting.

SEC. VI.—1. The Senators and Representatives shall receive a compensation for their services, to be ascertained by law, and paid out of the treasury of the United States. They shall, in all cases, except for treason, felony and breach of the peace, be privileged from arrest during their attendance at the session of their respective Houses, and in going to or returning from the same; and for any speech or debate in either House they shall not be questioned in any other place.

2. No Senator or Representative shall, during the time for which he was elected, be appointed to any civil office under the authority of the United States, which shall have been created, or the emoluments whereof shall have been increased during such time; and no person holding any office under the United States, shall be a member of either House, during his continuance in office.

SEC. VII.—1. All bills for raising revenues shall originate in the House of Representatives, but the Senate may propose or concur with amendments, as on other bills.

2. Every bill which shall have passed the House of Representatives and the Senate, shall, before it become a law, be presented to the President of the United States; if he approves, he shall sign it; but if not, he shall return it, with his objections, to that House in which it shall have originated, who shall enter the objections at large on their journal, and proceed to reconsider it. If, after such reconsideration, two-thirds of that House shall agree to pass the bill, it must be sent, together with the objections, to the other House, by which it shall likewise be reconsidered, and if approved by two-thirds of that House, it shall become a law. But in all such

cases the votes of both Houses shall be determined by yeas and nays; and the names of the persons voting for and against the bill, shall be entered on the journal of each House respectively. If any bill shall not be returned by the President within ten days (Sundays excepted) after it shall have been presented to him, the same shall be a law in like manner as if he had signed it, unless the Congress, by their adjournment, prevent its return; in which case it shall not be a law.

3. Every order, resolution, or vote, to which the concurrence of the Senate and House of Representatives may be necessary (except on a question of adjournment) shall be presented to the President of the United States; and before the same shall take effect, shall be approved by him, or being disapproved by him, shall be repassed by two-thirds of the Senate and House of Representatives, according to the rules and limitations prescribed in the face of a bill.

SEC. VIII.—The Congress shall have power—

1. To lay and collect taxes, duties, imposts and excises; to pay the debts, and provide for the common defence and general welfare of the United States; but all duties, imposts and excises shall be uniform throughout the United States:

2. To borrow money on the credit of the United States:

3. To regulate commerce with foreign nations and among the several States, and with the Indian tribes:

4. To establish a uniform rule of naturalization, and uniform laws on the subject of bankruptcies throughout the United States:

5. To coin money, regulate the value thereof, and of foreign coin, and fix the standard of weights and measures:

6. To provide for the punishment of counterfeiting the securities and current coin of the United States:

7. To establish post-offices and post-roads:

8. To promote the progress of science and useful arts by securing, for limited times, to authors and inventors, the exclusive right to their respective writings and discoveries:

9. To constitute tribunals inferior to the Supreme Court; to define and punish piracies and felonies committed on the high seas, and offences against the law of nations:

10. To declare war, grant letters of marque and reprisal, and make rules concerning capture on land and water:

11. To raise and support armies; but no appropriation of money to that use shall be for a longer term than two years:

12. To provide and maintain a navy:

13. To make rules for the government and regulation of the land and naval forces:

14. To provide for calling forth the militia to execute the laws of the Union, suppress insurrection and repel invasions:

15. To provide for organizing, arming and disciplining the militia, and for governing such part of them as may be employed in the service of the United States, reserving to the States respectively, the appointment of the officers, and the authority of training the militia, according to the discipline prescribed by Congress.

16. To exercise exclusive legislation, in all cases whatsoever, over such district (not exceeding ten miles square) as may, by cession of particular States, and the acceptance of Congress, become the seat of Government of the United States, and to exercise like authority over all places purchased by the consent of the Legislature of the State in which the same shall be, for the erection of forts, magazines, arsenals, dock-yards, and other needful buildings:—And

17. To make all laws which shall be necessary and proper for carrying into execution the foregoing powers, and all other powers vested by this Constitution in the Government of the United States, or in any department or officer thereof.

SEC. IX.—1. The migration or importation of such persons as any of the States now existing shall think proper to admit, shall not be prohibited by the Congress prior to the year one thousand eight hundred and eight; but a tax or duty may be imposed on such importation not exceeding ten dollars for each person.

2. The privilege of the writ of _habeas corpus_ shall not be suspended unless when, in cases of rebellion or invasion, the public safety may require it.

3. No bill of attainder, or _ex-post facto_ law, shall be passed.

4. No capitation, or other direct tax shall be laid, unless in proportion to the census or enumeration herein before directed to be taken.

5. No tax or duty shall be laid on articles exported from any State. No preference shall be given, by any regulation of commerce or revenue, to the ports of one State over those of another; nor shall vessels bound to or from one State, be obliged to enter, clear or pay duties in another.

6. No money shall be drawn from the treasury, but in consequence of appropriations made by law; and a regular statement or account of the receipts and expenditures of all public money, shall be published from time to time.

7. No title of nobility shall be granted by the United States; and no persons holding any office of profit or trust under them, shall, without the consent of the Congress, accept of any present, emolument, office or title, of any kind whatever, from any king, prince, or foreign state.

SEC. X.—1. No State shall enter into any treaty, alliance, or confederation; grant letters of marque and reprisal; coin money; emit bills of credit; make anything but gold and silver coin a tender in payment of debts; pass any bill of attainder, _ex-post facto_ law, or law impairing the obligation of contracts; or grant any title of nobility.

2. No State shall, without the consent of Congress, lay any imposts or duties on imports or exports, except what may be absolutely necessary for executing its inspection laws; and the net produce of all duties and imposts laid by any State on imports or exports, shall be for the use of the treasury of the United States; and all such laws shall be subject to the revision and control of the Congress. No State shall, without the consent of Congress, lay any duty of tonnage, keep troops or ships of war in time of peace, enter into any agreement or compact with another State, or with a foreign power, or engage in war, unless actually invaded, or in such imminent danger as will not admit of delay.

ARTICLE II.

SEC. I.—1. The executive power shall be vested in a President of the United States of America. He shall hold his office during the term of four years, and together with the Vice-President, chosen for the same term, be elected as follows:

2. Each State shall appoint, in such manner as the Legislature thereof may direct, a number of electors, equal to the whole number of Senators and Representatives to which the State may be entitled in Congress; but no Senator or Representative, or person holding an office of trust or profit under the United States, shall be appointed an elector.

3. [Annulled. See Amendments, Art. XII.]

4. The Congress may determine the time of choosing the elector, and the day on which they shall give their votes; which day shall be the same throughout the United States.

5. No person except a natural born citizen, or a citizen of the United States at the time of the adoption of this Constitution, shall be eligible to the office of President; neither shall any person be eligible to that office, who shall not have attained to the age of thirty-five years, and been fourteen years a resident within the United States.

6. In case of the removal of the President from office, or of his death, resignation, or inability to discharge the powers and duties of the said office, the same shall devolve on the Vice-President; and the Congress may by law provide for the case of removal, death, resignation, or inability, both of the President and Vice-President, declaring what officer shall then act as President, and such officer shall act accordingly, until the disability be removed, or a President shall be elected.

7. The President shall at stated times receive, for his services, a compensation, which shall neither be increased nor diminished during the period for which he shall have been elected; and he shall not receive within that period any other emolument from the United States or any of them.

8. Before he enter on the execution of his office he shall take the following oath or affirmation:

“I do solemnly swear (or affirm) that I will faithfully execute the office of President of the United States, and will, to the best of my ability, preserve, protect and defend the Constitution of the United States.”

SEC. II.—1. The President shall be Commander-in-Chief of the army and navy of the United States, and of the militia of the several States when called into actual service of the United States; he may require the opinion in writing of the principal officer in each of the executive departments, upon any subject relating to the duties of their respective offices; and he shall have power to grant reprieves and pardon for offences against the United States, except in cases of impeachment.

2. He shall have power, by and with the advice and consent of the Senate, to make treaties, provided two-thirds of the Senators present concur; and he shall nominate, and by and with the consent and advice of the Senate, shall appoint ambassadors, other public ministers, and consuls, judges of the Supreme Court, and all other officers of the United States, whose appointments are not herein otherwise provided for, and which shall be established by law. But the Congress may, by law, vest the appointment of such inferior officers as they think proper, in the President alone, in the courts of law, or in the heads of departments.

3. The President shall have power to fill up all vacancies that may happen during the recess of the Senate, by granting commissions which shall expire at the end of their next session.

SEC. III.—He shall, from time to time, give to the Congress information of the State of the Union, and recommend to their consideration such measures as he shall judge necessary and expedient; he may, on extraordinary occasions, convene both Houses, or either of them, and in case of disagreement between them, with respect to the time of adjournment, he may adjourn them to such time as he shall think proper; he shall receive ambassadors and other public ministers; he shall take care that the laws be faithfully executed, and shall commission all the officers of the United States.

SEC. IV.—1. The President, Vice-President and all civil officers of the United States shall be removed from office on impeachment for, and conviction of, treason, bribery or other high crimes and misdemeanors.

ARTICLE III.

SEC. I.—1. The judicial power of the United States shall be vested in one Supreme Court, and in such inferior courts as the Congress may, from time to time, ordain and establish. The judges, both of the Supreme and inferior courts, shall hold their offices during good behavior, and shall, at stated times, receive for their services a compensation, which shall not be diminished during their continuance in office.

SEC. II.—1. The judicial power shall extend to all cases in law and equity arising under this Constitution, the laws of the United States, and treaties made, or which shall be made, under their authority; to all cases affecting ambassadors, other public ministers and consuls; to all cases of admiralty and maritime jurisdiction; to controversies to which the United States shall be a party; to controversies between two or more States, between a State and citizens of another State, between citizens of different States, between citizens of the same State claiming lands under grants of different States, and between a State or the citizens thereof, and foreign States, citizens or subjects.

2. In all cases affecting ambassadors, other public ministers and consuls, and those in which a State shall be a party, the Supreme Court shall have original jurisdiction. In all the other cases before mentioned, the Supreme Court shall have appellate jurisdiction, both as to law and fact, with such exceptions and under such regulations as the Congress may make.

3. The trial of all crimes, except in cases of impeachment, shall be by jury; and such trial shall be held in the State where the said crimes shall have been committed; but when not committed within any State, the trial shall be at such place or places as the Congress may by law have directed.

SEC. II.—1. Treason against the United States shall consist only in levying war against them, or in adhering to their enemies, giving them aid and comfort. No person shall be convicted of treason unless on the testimony of two witnesses to the same overt act, or on confession in open court.

2. The Congress shall have power to declare the punishment of treason; but no attainder of treason shall work corruption of blood, or forfeiture, except during the life of the person attainted.

ARTICLE IV.

SEC. I.—1. Full faith and credit shall be given, in each State, to the public acts, records and judicial proceedings of every other State. And the Congress may, by general laws, prescribe the manner in which such acts, records and proceeding, shall be proved, and the effect thereof.

SEC. II.—1. THE CITIZENS OF EACH STATE SHALL BE ENTITLED TO ALL PRIVILEGES AND IMMUNITIES OF CITIZENS IN THE SEVERAL STATES.

2. A person charged in any State with treason, felony or other crime, who shall flee from justice, and be found in another State, shall, on demand of the executive authority of the State from which he fled, be delivered up to be removed to the State having jurisdiction of the crime.

3. No person held to service or labor in one State, under the laws thereof, escaping into another, shall, in consequence of any law or regulation therein, be discharged from such service or labor; but shall be delivered up, on claim of the party to whom such service or labor may be due.

SEC. III.—1. New States may be admitted by the Congress into this Union; but no new State shall be formed or erected within the jurisdiction of any other State, nor any State be formed by the junction of two or more States, or parts of States, without the consent of the Legislature of the States concerned, as well as of the Congress.

2. The Congress shall have power to dispose of and make all needful rules and regulations respecting the territory or other property belonging to the United States; and nothing in this Constitution shall be so construed as to prejudice any claims of the United States or of any particular State.

SEC. IV.—THE UNITED STATES SHALL GUARANTEE TO EVERY STATE IN THIS UNION A REPUBLICAN FORM OF GOVERNMENT, AND SHALL PROTECT EACH OF THEM AGAINST INVASION; AND, ON APPLICATION OF THE LEGISLATURE, OR OF THE EXECUTIVE (WHEN THE LEGISLATURE CANNOT BE CONVENED), AGAINST DOMESTIC VIOLENCE.

ARTICLE V.

The Congress, whenever two-thirds of both Houses shall deem it necessary, shall propose amendments to this Constitution; or, on the application of the Legislatures of two-thirds of the several States, shall call a convention for proposing amendments, which, in either case, shall be valid to all intents and purposes, as part of this Constitution, when ratified by the Legislatures of three-fourths thereof, as the one or the other mode of ratification may be proposed by Congress; provided that no amendment which may be made prior to the year one thousand eight hundred and eight, shall, in any manner, affect the first and fourth clauses in the ninth section of the first article; AND THAT NO STATE, WITHOUT ITS CONSENT, SHALL BE DEPRIVED OF ITS EQUAL SUFFRAGE IN THE SENATE.

ARTICLE VI.

1. All debts contracted, and engagements entered into, before the adoption of this Constitution, shall be as valid against the United States under this Constitution, as under the Confederation.

2. This Constitution, and the laws of the United States which shall be made in pursuance thereof, and all treaties made, or which shall be made under the authority of the United States, shall be the supreme law of the land; and the judges in every State shall be bound thereby; anything in the Constitution or laws of any State to the contrary notwithstanding.

3. The Senators and Representatives before mentioned, and the members of the several State Legislatures, and executive and judicial officers both of the United States and of the several States, shall be bound by oath or affirmation to support this Constitution; but no religious test shall ever be required as a qualification to any office, or public trust, under the United States.

ARTICLE VII.

The ratification of the convention of nine States shall be sufficient for the establishment of this Constitution between the States so ratifying the same.

GEORGE WASHINGTON, President.

WILLIAM JACKSON, Secretary.

AMENDMENTS TO THE CONSTITUTION.

ARTICLE I.

Congress shall make no law respecting an establishment of religion, or prohibiting the free exercise thereof; or abridging the freedom of speech, or of the press; or the right of the people peaceably to assemble and to petition the Government for a redress of grievances.

ARTICLE II.

A well regulated militia being necessary to the security of a free State, the right of the people to keep and bear arms shall not be infringed.

ARTICLE III.

No soldier shall, in time of peace, be quartered in any house without the consent of the owner; nor in time of war, but in a manner to be prescribed by law.

ARTICLE IV.

The right of the people to be secure in their persons, houses, papers and effects, against unreasonable searches and seizures, shall not be violated; and no warrant shall issue but upon probable cause, supported by oath or affirmation, and particularly describing the place to be searched, and the persons or things to be seized.

ARTICLE V.

No person shall be held to answer for a capital or otherwise infamous crime, unless on a presentment or indictment of a grand jury, except in cases arising in the land or naval forces, or in the militia, when in actual service, in time of war or public danger; nor shall any person be subject, for the same offence, to be twice put in jeopardy of life or limb; nor shall he be compelled, in any criminal case, to be a witness against himself, nor be deprived of life, liberty or property without due process of law; nor shall private property be taken for public use without just compensation.

ARTICLE VI.

In all criminal prosecutions the accused shall enjoy the right to a speedy and public trial by an impartial jury of the State and district wherein the crime shall have been committed, which district shall have been previously ascertained by law, and to be informed of the nature and cause of the accusation; to be confronted with the witnesses against him; to have compulsory process for obtaining witnesses in his favor, and to have the assistance of counsel for the defence.

ARTICLE VII.

In suits at common law, where the value in controversy shall exceed twenty dollars, the right of trial by jury shall be preserved; and no fact tried by a jury shall be otherwise re-examined in any court of the United States than according to the rules of the common law.

ARTICLE VIII.

Excessive bail shall not be required, nor excessive fines imposed, nor cruel and unusual punishments inflicted.

ARTICLE IX.

The enumeration in the Constitution of certain rights shall not be construed to deny or disparage others retained by the people.

ARTICLE X.

The powers not delegated to the United States by the Constitution, nor prohibited by it to the States, are reserved to the States respectively, or to the people.

ARTICLE XI.

The judicial power of the United States shall not be construed to extend to any suit in law or equity commenced or prosecuted against one of the United States by citizens of another State, or by citizens or subjects of any foreign State.

ARTICLE XII.

1. The electors shall meet in their respective States, and vote by ballot for President and Vice-President, one of whom, at least, shall not be an inhabitant of the same State with themselves; they shall name in their ballots the person voted for as President, and in distinct ballots the person voted for as Vice-President; and they shall make distinct lists of all persons voted for as President and of all persons voted for as Vice-President, and of the number of votes for each, which list they shall sign and certify, and transmit sealed to the seat of Government of the United States, directed to the President of the Senate; the President of the Senate shall, in the presence of the Senate and House of Representatives, open all the certificates, and the votes shall then be counted; the person having the greatest number of votes for President shall be the President, if such number be a majority of the whole number of electors appointed; and if no one has such majority, then, from the persons having the highest numbers, not exceeding three, on the list of those voted for as President, the House of Representatives shall choose immediately, by ballot, the President. But in choosing the President, the votes shall be taken by States, the representation from each State having one vote; a quorum for this purpose shall consist of a member or members from two-thirds of the States, and a majority of all the States shall be necessary to a choice. And if the House of Representatives shall not choose a President, whenever the right of choice shall devolve upon them, before the fourth day of March next following, then the Vice-President shall act as President, as in the case of the death or other constitutional disability of the President.

2. The person having the greatest number of votes as Vice-President shall be the Vice-President, if such number be a majority of the whole number of electors appointed; and if no person have a majority, then, from the two highest numbers on the list, the Senate shall choose the Vice-President; a quorum for the purpose shall consist of two-thirds of the whole number of Senators, and a majority of the whole number shall be necessary to a choice.

3. But no person constitutionally ineligible to the office of President shall be eligible to that of Vice-President of the United States.

ARTICLE XIII.

If any citizen of the United States shall accept, claim, receive or retain any title of nobility or honor, or shall, without the consent of Congress, accept and retain any present, pension, office or emolument, of any kind whatever, from any emperor, king, prince or foreign power, such person shall cease to be a citizen of the United States, and shall be incapable of holding any office of trust or profit under them or either of them.

ARTICLE XIV.

1. All persons born or naturalized in the United States, and subject to the jurisdiction thereof, are citizens of the United States and of the State wherein they reside. No State shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States. Nor shall any State deprive any person of life, liberty or property without due process of law, nor deny to any person within its jurisdiction the equal protection of the laws.

2. Representatives shall be appointed among the several States according to their respective numbers, counting the whole number of persons in each State, excluding Indians not taxed; but whenever the right to vote at any election for electors of President and Vice-President, or for United States Representatives in Congress, executive and judicial officers, or the members of the Legislature thereof, is denied to any of the male inhabitants of such State, being twenty-one years of age and citizens of the United States, or in any way abridged, except for participation in rebellion or other crime, the basis of representation therein shall be reduced in the proportion which the number of such male citizens shall bear to the whole number of male citizens twenty-one years of age in that State.

3. No person shall be a Senator or Representative in Congress, elector of President or Vice-President, or hold any office, civil or military, under the United States, or under any State, who, having previously taken an oath as member of Congress, or as an officer of the United States, or as a member of any State Legislature, or as an executive or judicial officer of any State, to support the Constitution of the United States, shall have engaged in insurrection or rebellion against the same, or given aid or comfort to the enemies thereof; but Congress may, by a vote of two-thirds of each House, remove such disability.

4. The validity of the public debt of the United States, authorized by law, including debts incurred for the payment of pensions and bounties for service in suppressing insurrection or rebellion, shall not be questioned, but neither the United States nor any State shall assume or pay any debt or obligation incurred in aid of insurrection or rebellion against the United States, or claim for the loss or emancipation of any slave, but all such debts, obligations and claims shall be held illegal and void.

ARTICLE XV.

The right of citizens of the United States to vote shall not be denied or abridged by the United States, or by any State, on account of race, color or previous conditions of servitude.

[Revised from the New York Herald of April 2, 1870.]

FIRST PRONUNCIAMENTO.

The disorganized condition of parties in the United States at the present time affords a favorable opportunity for a review of the political situation and for comment on the issues which are likely to come up for settlement in the Presidential election in 1872. As I happen to be the most prominent representative of the only unrepresented class in the republic, and perhaps the most practical exponent of the principles of equality, I request the favor of being permitted to address the public through the medium of the _Herald_. While others of my sex devoted themselves to a crusade against the laws that shackle the women of the country, I asserted my individual independence; while others prayed for the good time coming, I worked for it; while others argued the equality of woman with man, I proved it by successfully engaging in business; while others sought to show that there was no valid reason why women should be treated, socially and politically, as being inferior to man, I boldly entered the arena of politics and business and exercised the rights I already possessed. I therefore claim the right to speak for the unenfranchised women of the country, and believing as I do that the prejudices which still exist in the popular mind against women in public life will soon disappear, I now announce myself as candidate for the Presidency.

I am quite well aware that in assuming this position I shall evoke more ridicule than enthusiasm at the outset But this is an epoch of sudden changes and startling surprises. What may appear absurd to-day will assume a serious aspect to-morrow. I am content to wait until my claim for recognition as a candidate shall receive the calm consideration of the press and the public. The blacks were cattle in 1860; a negro now sits in Jeff Davis' seat in the United States Senate. The sentiment of the country was, even in 1863, against negro suffrage; now the negro's right to vote is acknowledged by the constitution of the United States. Let those, therefore, who ridiculed the negro's claim to exercise the right to "life, liberty and the pursuit of happiness," and who lived to see him vote and hold high public office, ridicule the aspirations of the women of the country for complete political equality as much as they please. They cannot roll back the rising tide of reform. The world moves.

That great Governmental changes were to follow the enfranchisement of the negro I have long foreseen. While the curse of slavery covered the land progress was enchained, but when it was swept away in the torrent of war, the voice of justice was heard, and it became evident that the last weak barrier against complete political and social equality must soon give way. All that has been said and written hitherto, in support of equality for women has had its proper effect on the public mind, just as the anti-slavery speeches before secession were effective; but a candidate and a policy are required to prove it. Lincoln's election showed the strength of the feeling against the peculiar institution; my candidacy for the Presidency will, I confidently expect, develop the fact that the principles of equal rights for all have taken deep root. The advocates of political equality for women have, besides a respectable known strength, a great undercurrent of unexpressed power, which is only awaiting a fit opportunity to show itself. By the general and decided test I propose, we shall be able to understand the woman question aright, or at least have done much toward presenting the issue involved in proper shape. I claim to possess the strength and courage to be the subject of that test, and look forward confidently, to a triumphant issue of the canvass.

The present position of political parties is anomalous. They are not inspired by any great principles of policy or economy. Political preachers paw the air; there is no live issue up for discussion. The only seemingly distinctive feature upon which a complete and well-defined diversion exists, is on the dead issue of negro equality, and this is to the political leaders a harp of a thousand strings.

The minor questions of the hour do not affect parties as such, and no well-defined division of sentiment exists. A great national question is wanted, to prevent a descent into pure sectionalism. That question exists in the issue, whether woman shall remain sunk below the right granted to the negro, or be elevated to all the political rights enjoyed by man. The simple issue whether woman

should not have this complete political equality with the negro is the only one to be tried, and none more important is likely to arise before the Presidential election. But besides the question of equality others of great magnitude are necessarily included. The platform that is to succeed in the coming election must enunciate the _general_ principles of enlightened justice and economy.

A complete reform in our system of prison discipline, having specially in view the welfare of the families of criminals, whose labor should not be lost to them; the rearrangement of the system and control of internal improvements; the adoption of some better means for caring for the helpless and indigent; the establishment of strictly mutual and reciprocal relations with all foreign Powers who will unite to better the condition of the productive class, and the adoption of such principles as shall recognize this class as the true wealth of the country, and give it a just position beside capital, thus introducing a practical plan for universal government upon the most enlightened basis, for the actual, not the imaginary benefit of mankind.

These important changes can only be expected to follow a complete departure from the beaten tracks of political parties and their machinery; and this, I believe my canvass of 1872 will effect.

That the people are sick of the present administration and the principles it professes to sustain, is a proposition, I think, that does not require to be argued; but as I have now taken a decided stand against its continuance for another term of four years, and offered myself as a candidate for the Presidential succession, a few preliminary observations on the general management of our home and foreign policy will not be out of place. The present administration has been a failure from the beginning; weak, vacillating and deficient in moral courage, it commands neither the respect nor admiration of foreign Powers nor receives the active support of its party. The general management of our foreign and domestic affairs does not seem to have risen to the dignity of a policy; though it be allowed to have been consistent in its various parts, it has been destitute of that decision and firmness which characterized the victorious soldier who is now President.

A decided Cuban policy would not only have settled at once the inevitable destiny of that island, but would also have given republican sentiment in Spain an impetus, strengthened the South American republics and exercised a healthy influence in Mexico and Canada. But instead of this we have to submit to the consequences of a policy of cowardice. American citizens abroad are murdered by Spanish cut-throats, our consuls are insulted, and our flag is disgraced. This is unworthy of the American nation, and the people will hold Grant accountable. A giant who never shows his strength is neither feared nor respected. On the important questions of taxation, the tariff and the public debt, the administration seems to have no settled policy. Taxation, whether for the support of the Government or the payment of the debt, should in all cases be general and never special. No special interest, nor several special interests, should be singled out to sustain an extra proportion of taxation. And in regard to the tariff the same principle should be enforced. Whether the public debt be a blessing or a curse, it exists. Created to save the republic, it must be paid strictly according to both the spirit and the letter of the law. But there is no immediate necessity for paying it off. By a proper policy its payment might be made to extend through a hundred years, for even beyond that time will the benefits its creation produced be felt and appreciated. In older countries the pressure of national debt becomes a heavier charge and a mightier burden every succeeding year, but with us this is reversed. The development of our magnificent resources will render the gradual payment of our indebtedness easier of accomplishment with each decade of time.

All other questions, whether of a foreign or domestic nature, stand illustrated by the Cuban policy of the administration. A bold, firm and, withal, consistent national policy, if not at all times strictly within the conservative limits of international law, will always command the respect and support of the people.

With the view of spreading to the people ideas which hitherto have not been placed before them, and which they may, by reflection, carefully amplify for their own benefit, I have written several papers on Governmental questions of importance and will submit them in due order. For the present the foregoing must suffice. I anticipate criticism; but however unfavorable the comment this letter may evoke I trust that my sincerity will not be called in question. I have deliberately and of my own accord placed myself before the people as a candidate for the Presidency of the United States, and having the means, courage, energy and strength necessary for the race, intend to contest it to the close.

VICTORIA C. WOODHULL.

A VIEW OF THE GENERAL SITUATION.

NEW YORK, November 10, 1870.

In national as well as in individual affairs, it is well to occasionally take an exact account of the situation in which we are; to balance “our general books,” to see whether the balance is to the “debit or credit” or “profit and loss,” and to decide from the results obtained whether satisfactory progress has been made. As nothing more than “a journal” of such affairs as we shall take into the account has been kept, it will be our duty to “post” these affairs into a new “ledger” from existing “journals,” and also to enter up the new balances which we may find standing to the several accounts.

At no time since the close of the Revolutionary War has there been a time more fitting and inviting for such a work. The whole world is in a ferment, which was begun by the terrific strife into which the course of events forced us, and from which we have just emerged through the reconstruction of an almost demolished Governmental structure. Not all of the legitimate results of that strife are even yet externally apparent, either in our own country or in the world at large. There are various undercurrents, eddies and outcroppings which have never been taken into any consideration; but when considered, the destiny of this country, so long foreshadowed, but which was pretty nearly eclipsed, shines forth more clearly brilliant than ever before.

Whatever may have been the arguments favorable for the continuance of the institution of slavery, the destruction of it has rendered them nugatory, and but few of those who once used them could now be found to favor its resurrection. The atmosphere is cleared of the cloud it was draped with, under its influence, and the radiant sun of freedom now shines for all, and the star of hope our night was illumined by shall now no more be dimmed by the dense fogs that were wont to arise from its then already decaying carcass. With its destruction the lives of two great political parties passed away, and left the people with no distinct lines of demarkation. It is true that there bodies still exist, but the process of disintegration is rapidly going on, and the stench of their decay fills the nostrils of all whose senses are rendered acute by the intensifying power of intuitive perception.

Creation is from one point toward one purpose, the extremes of which course, are beyond the comprehension of human ken. Any fact in the line of its progress may be considered, and the relations it bears to contemporaneous facts determined. A fact isolated from all connections loses its significance. The comparison of a fact with other facts forms the basis of all relative knowledge, and the further this comparison is extended, the wider the range of this knowledge becomes: while an infinite series of facts constitutes the sum total of creation.

Hence, to obtain a substantially correct knowledge of the present, the facts of it must not only be considered as facts of the present, but their relations to, and dependencies upon prior facts, out of which they arose, must be traced, so that it may be determined why they exist. It is not sufficient to simply assert that this or that is thus or so. To do so carries no conviction nor prophetic knowledge of what must be next, as a necessary sequence. But if a retrospective glance be taken of the causes that produced it, it is thus demonstrated why it is thus. If the demonstration is placed with the fact, and their tendencies are examined, it may be fair to conclude that what they may next lead to, may be in a measure predicated. The chief value, then, of an intimate knowledge of the past is, that from it the future may be foreseen, and that the lesson it teaches may assist in the formation of aids to the natural order of things.

If a tree or plant is desired in a certain place, for a certain purpose, its growth is promoted by all the means which experience has demonstrated will assist. All other growths that draw from the same source for supplies, and thereby diminish its fountain of supplies, are destroyed; the weeds are uprooted, and if the natural supplies which the earth and air furnish are not sufficient for its demands, that which is lacking is supplied. The same line of action should govern in the various departments of nature, and especially in the higher departments of mind.

There is another consideration that should never be lost sight of when a survey of the situation is to be attempted; and this is, that while the facts which are to be passed upon bear special relations to their immediate predecessors and surroundings, that these with them bear certain definite, general relations to the facts of all past time, and to those that will be in all future time. The present is a part of the common order of the universe, extending infinitely backward and forward—a part of the line of evolvement, neither end of which can be compassed by human mind; and if we would learn well, we must learn all there is to learn regarding what we learn.

It is a definite and unanswerable proposition, then, that every nation of which we have historic record, was a result of pre-existing causes, and led to further effects, and that each filled and performed a part, especially its own, which was a natural and necessary result of the time and place it existed in. By a careful study of the rise and fall of each of the great nations that have existed and an analytic comparison of the elements of strength and decay that were prominent therein, and of their relations to each other, just deductions as to what the present will lead to, may be arrived at. If the present is the result of the past, the future must be the result

of the present, and like it be the experiences of creation in the process of evolution from the infinite to the infinite.

Government, standing forth prominently as the grandest of all human conceptions and realizations, has in all times been the representative of civilization, and the principal means of its diffusion. Bearing this impress of importance, it may be well to examine the real significance of the term, or to find the relations it sustains to society. One fact meets us wherever we may search in the past—the fact of government Though it is one of the universal necessities and accompaniments of existence, it is extremely doubtful if its composition is realized to any considerable extent. Government means control—implies power. No people can create government because they cannot create power. An existing power may be organized into form by a people, and this becomes their government. This power is not in the individuals who exercise it, they are simply its servants. It is not the people who organize or consent to it; they are simply represented by it. It is above individuals, and is independent of peoples, though its channels of operation may be modified by individuals and peoples. Thus come all governments, while revolutions are the results of the outworking of principles, through peoples, who are their representatives. When analyzed, it thus appears that governments are independent of peoples, and always exist in some form while peoples come and pass away.

It is problematically true, that China was the first nation that arrived at a system of government at all removed from brute, individual force, and historically so, that there always was a westward tendency to empire. After China, India; then Assyria, Egypt, Persia, Greece, Rome, general Europe and America. Each one of these nations, to Rome, was the result of the course of events, begun in China, to the course of which each succeeding one added its experiences. The progress of this course of events has encircled the world. It can go no further westward without crossing the Pacific and beginning again in China. What is the significance of this fact, or has it no special indications? It is evident that the old order of nature has completed a cycle, and that a new order will be commenced, and that, the new order is to spring from this country, and consequently, that we are its representatives. This is made doubly plain, when we refer to the fact that Asiatic tendencies are now eastward, and that John Chinaman is the new competition our laboring classes have to encounter.

It cannot be expected that the new order of events, we, as a country are inaugurating, will be characterized by the element of the old, just completed. It had its mission to perform. It accomplished it, and has passed away. Its fruit is our Government and the civilization of the present. A new mission begins. Are there any sources from which its character may be predicated? Though the creation has completed another cycle of progressive development, the common course of nature never stops. Therefore the same common order prevails now, that did when the planes of Iran poured forth its people westward.

One of the principal features of natural events has been a tendency on the part of all great nations to acquire universal dominion. Each in turn attempted it and failed, because of the imperfectly developed form of the government they sought to control by. What are the evidences that all future forms may not fail from similar causes, or specially, that the form we represent will not fail?

The first and most important evidence is, that in its organic principles the Brotherhood of the Human Race is recognized. All men are born free and equal, does not mean that all men born in the United States are free and equal, but that all men everywhere are. This, then, is the basis idea upon which our Government is built; whether the structure is yet perfect or not the foundation is, and can never be overturned. There can be no higher proposition upon which to build; therefore additions, tending to perfectability, must be made upon this foundation.

Another evidence is, that the world is becoming Americanized: that is, the world is assimilating to the American idea of freedom and equality. How and why? The vast populations other countries have transplanted to our soil are in constant communication with friends they left behind, who thus catch the spirit of equality and freedom, and become imbued with the spirit of our institutions, and thus involuntarily become like us, while still subjects of other powers.

All nations contribute to our strength, and by so doing render us not only peculiarly American in character, but cosmopolitan to the world. We are not only American, but European, Asiatic and African; while each of these are becoming American. We are, therefore, the centre of attraction for the world, and the world involuntarily recognizes our superior strength by giving up its population to increase it; while we repay it, not in physical strength, but with progressive and comprehensive ideas. In accordance with these facts, patent to every one, it is asserted, that The World is becoming Americanized, and that this is an evidence that the form of government by which we tend to universal control is founded on those general principles which give it that permanency, which insures its continuance until it shall become universal.

If the order of civilization is observed the same deduction will be arrived at The material universe has had its geologic periods The social has had and will have its periods to correspond. Nature maintains a regular and consistent order everywhere. It is the degree

that this order is understood, by the general mind, that constitutes the sociologic periods of the world. The first era of civilization was inaugurated by the Assyrian and Egyptian empires, more especially the latter, more than 2000 years B. C.

This civilization began to spread in the barbaric world immediately after the famous conquests of Sesostris, and continued during the time of the Persian, Grecian and Roman empires, culminating with the downfall of the latter, and thus completing the order of civilization made possible by Egypt. Egypt conquered and levied tribute upon the barbarian. Rome conquered, and the barbarian became the Roman citizen. The present configuration of Europe rose from the ruins of Rome, and assumed the form through which a greater variety of power could operate than in the previous era.

No part of the world but has felt the mighty modifying influence of the civilizing power of modern Europe. It has permeated the entire temperate zone, penetrated the frozen latitudes north and south, and attacked the Hottentot of Central Africa and the Bushman of Australia. It organized legislation, perfected and maintained administration and made it possible for all minds to attain individuality, and for individuals, as such, to rise by personal merit, even from the lowest strata of society. By its procreative power a new continent, full of native purity and vitality, conceived, and a higher degree of life than it represented burst upon the startled world.

In the first era, it was one controlling mind operating for personal ends and aggrandizement; in the second, it was several, operating for the same end; in the third, it will be all minds merged in one channel, to operate for the good of the whole. The first was personal civilization thrust upon the barbarism of the world compelling it into servility; the second was sectional civilization exerting its influence, first upon its immediate subjects, and through them upon others less advanced; the third shall be general civilization, in which the utmost parts of the earth can join in one grand and common effort for mutual advancement, its peoples having risen to the recognition of the greatest of all human facts—the common brotherhood of mankind.

From these general observations the tendencies in the order of the universe must be inferred, and if there is any inference possible to be drawn, which will coincide with the present aspect of affairs, it is, that upon this country devolves the duty, no less than the privilege, of presenting the world with a form of administrative government that shall be possessed of the elements of perfection and duration; and this brings us down to the consideration, whether this general indication of the centuries does coincide with the condition in which the world is to-day.

Europe contains but four positive determining powers: Russia, Prussia, France and England, while the remainder of the Eastern Continent is unrepresented. The Western Continent contains the United States. France and Prussia have been the contending parties for simple European supremacy: the former probably also entertaining an ulterior design upon Africa. The policy of England and Russia is more comprehensive, and undoubtedly includes the possibility of a consolidated Continent. Consistent with this view, England is performing in India what Cæsar did in Gaul; and Russia, in Western Asia, what Rome did in “The East.” They comprehend that every nation is an object upon which change is indelibly stamped, and that it will remain so until some one of them shall arrive at a perfect system of government, which shall be the pattern for all government, or which shall absorb all government. These countries labor under one insurmountable difficulty. All the effort they expend to carry their policies abroad detracts just so much from their actual home strength, and they have no fountain, furnishing supplies to make good their expenditure, and they thus expand at the expense of vitality.

Notwithstanding this great difficulty, Russian supremacy might be a consistent conclusion, could the fact of the rapid diffusion of principles antagonistic to monarchy be left out of the consideration; but considered, as it necessarily must be, the legitimate conclusion is entirely different. It is too well known what sentiments lie suppressed in various parts of continental Europe—in Poland, Hungary, Italy, France, Germany, Spain and England—to ever make it possible that the common order of advancement should so change as to compel the general mind from general freedom toward absolute monarchy, as represented by Russia, or to any monarchy represented by any of the nations of Europe. The common course of events will not so change, but it will continue in the direction of general freedom, not only in Europe but over the entire continent. Considering the progress this sentiment has already made in connection with events which are transpiring in Europe, it is not presuming very much to say that it will ultimately convert Western and Central Europe into great republics, represented by the Latin and the Teuton.

So much for the special situation of Europe proper, as connected with its local policies. England and Russia have further reaching pretensions, and, by so having, their policies become intermingled with American policies.

The processes of civilization are soon to receive accelerating powers in Asia. England, by virtue of her great commercial influence, has already exerted very considerable modifying effect upon the vast population of India. China, by its fickle action regarding foreigners resident there, is claiming the attention of all interested countries, in such manner as will undoubtedly force these

countries to use some other than moral suasion to compel its people to the common usages of the civilized world. Thus barbarism invites the elements which ultimately transform it into general worldly utility.

With China, the United States has more intimate connection, by reason of recent scientific progress, and, with England, will divide the honor of civilizing Eastern Asia. American influence, however, will be the preponderant influence, for the Chinese are attracted to this country, and the genius of our institutions cannot fail to react through such as come here upon China itself. While this process of evolution is going on in Eastern Asia, Russia will be effecting the same purposes in Western Asia, and thus these three nations will in due course of time reclaim the most densely populated part of the world and add it to the sum total of civilization.

There is a very important and highly suggestive inference to be drawn from the tendency the peoples of Europe have been exhibiting during the past few years. Italian unity has been accomplished, and German unity is about to be accomplished. It is not to be supposed that this process will stop short of further consolidations. Continental Europe is Latin and Teuton, and Slav, and this process cannot well cease until these are united under their respective governments. When this shall have been accomplished, thrones and crowns will have done their work, and the peoples will be ready to erect the Latinic, the Teutonic, and the Slavonic Republics, three mighty nations which could in peace and quiet pursue their respective appointments in the path of progress, until a necessity should arise for a still wider and more comprehensive unity, in which, under one head, the three should be united. They who have studied the general tendencies of governmental evolution cannot doubt but such a consummation awaits Continental Europe, nor that Asia is destined to be regenerated as above shadowed forth.

If such be the course events must take, what is the lesson to be gathered by that part of the world's people who speak the English language? The location of the countries they inhabit does not so readily point to unity, but all their interests will compel it. The nations of the world instinctively seek equality of power, or rather, they seek to keep pace with each other in acquiring power. In view of the prospective union of the three dominant races in Continental Europe, where shall England look for her compensating power, except it be in a unity of all peoples speaking the English Language?

It is true that in this Western Continent there is a new race being built up, in whose composition all other races are destined to become blended, and which will inevitably be the dominant and the absorbing future race of the world. However, in the mean time, England's only hope for the retention of an existence, or at least of any general power, will be to unite its peculiar national characteristics to the younger and more rapidly changing peoples of America. There might be reasons without number adduced in support of the suggested course, while valid ones against it cannot be found. The power such a nation would represent would be one that neither nor all of the prospective Continental European countries could hinder from pursuing its predestined work in Asia and Africa, to which latter division enterprise is just being attracted by the discovery of immense diamond countries, which are first offered as the necessary temptation to draw people to it, who shall afterward find other riches than precious stones within its virgin soil, as other than golden wealth has been found in California.

Thus, in as comprehensive a manner as possible, is presented the present general situation and its evident tendencies, which bring us to the special consideration of the present condition of the country, which, of all countries, is destined to play the most prominent part in the third order of civilization—the United States of America.

We have just arisen mightier than ever from a civil war which was intended by the world's conservatism to destroy us, and with a population of forty millions we step at once into the front ranks of, and into the lead in, the grand march of progress. Our Government is a nearer approach to a popular form, and more nearly allied to true freedom and justice than any other in existence. We have, however, only to review the causes which led to the civil war to see how far we still are from a perfect form.

This war was either a necessary result of existing causes or else it was a great national blunder. Many who recognize no order or law in the progress of civilization, deny both these propositions, and affirm that the war was produced solely by the personal ambition of party leaders, representing the _pro_ and _con._ of the institution of slavery. If the matter is viewed from the standpoint of the science of society, each one of these propositions is relatively true, but neither is absolutely so. The war was the necessary result of the growth of the principles of freedom within the general mind, in antagonism to special, local interests, which evidences that it did arise naturally, out of the existing conditions, while the individuals who were prominent upon either side may be considered as responsible for precipitating it. Those who stood by, constituting much the larger proportion of the representative men of the nation, and observed the growth of the conflict between the two extremes, without stepping in to control the situation, place it altogether in the light of a great national blunder or crime. Had the circumstances been controlled by this large third party, the first proposition would have been true, and yet the war have been prevented.

We are obliged to speak relatively of relative things, and to consider facts, isolated from the general sum of all facts, and in a special sense, and in this sense the war was an enormous national blunder, and should have been averted by a bold grasping and control of the circumstances on the part of the Government and those whose _duty_ it was to have known what the result would be. These servants of the people, to whom was intrusted the welfare of the country, were utterly false and faithless, and allowed us to be precipitated, entirely unprepared, into a fratricidal war which cost the common country millions of lives and billions of treasure.

How much better would it have been had the situation been understood and controlled; had the Government shown itself competent to meet it; had it raised armies and occupied the disaffected country and then abolished slavery, which it was finally obliged to do, but which could have been done previously without the sacrifice of life and wealth. Such action would have exhibited the highest order of statesmanship and would have been the admiration of ages.

This examination of the causes which led to the war is made to show, that in our system of government as now administered, there is no responsibility anywhere, and if we drift into danger and destruction no one is accountable; and also, that it is the habitual practice, to evade issues which press for solution, by dodging along with small expedients, hoping the issues themselves will die out or pass away. This has been true of us as a government since corruption first began to find its emissaries among our legislators, and since, it has continually grown more and more decidedly a feature of its administration, until to-day we stand a gigantic nation without giving any indication that we realize our power or that we have any national policy other than to be quite certain that we do not interfere with any of the nice arrangements of other nations, or that we do not lend struggling freedom a sympathetic helping hand, such as we first acquired life by.

By whom are our legislative halls filled? Do we find any Jeffersons, Jacksons, Hamiltons, Bentons, Websters or Clays among them? No! As a rule, to which, however, there a few most honorable exceptions, there are all small men with ideas no more comprehensive than the districts or States they represent, and who make the purposes of personal gain the mainspring of all their actions. What can such men thus employed, know of a great nation’s power; or what her policy should be?

There have been two great political divisions of the people called Republican and Democratic, the issue between which, grew entirely out of the slavery question and its sequel, War and Reconstruction. These issues are all settled. Slavery can never more be made a party issue. All efforts that have been made to galvanize it into life have proved futile. The Democratic party leaders have pretty nearly given up the issue as utterly dead, though many of the rank and file still mouth “the nigger.” The Republican party has absolutely nothing to make it hold together except possession of place and power, which in these times of levying official taxation is no inconsiderable advantage. As for issues and policies, both parties absolutely lack them. The Democratic and Republican parties exist to-day in opposition to each other, simply and solely because they were opposed to each other upon the issues now dead. No live issues divide them. All of these which are before the people find advocates and opposers in both ranks, so that in reality there are no political parties in existence which represent any question to be solved or settled. Nothing could be more appropriate in the political musterings and parades of either party than that upon their banners should be inscribed—

WANTED, A POLICY.

It is evident, if another Presidential canvass passes over, that some grand issue must come up to give the people inspiration, and which will be of such character as to _divide_ them, not such as would _unite_ them unanimously; for to this last condition, it is to be feared, we have not yet arrived _though there may be such things arise as will command as much unanimity_ as Washington commanded; but this could not be, _except revolution_ occurs and it becomes the result of it.

With a young intelligence such as we represent, no old issues can be made to divide parties. Upon such questions as have heretofore been made the distinguishing features of political parties, there should be no misunderstanding. That there is, demonstrates that the principles of government have not been taught to the people. It teaches that party leaders have built up theories which lack the support of science and principle; and in this way all those issues upon which the permanent vitality of the country depends have been put before the people, colored and trimmed to suit their prejudices and to shape parties into opposition. Were all of these issues taught to the people as the legitimate deduction of the science of government, and entirely bereft of partisanship, they would all work together for the obtaining of more, greater and better conditions and privileges. To bring about this course for the people is the object of the science of society which is just beginning to be recognized.

There are but three principles by which all questions should be tested: Freedom, Equality and Justice; and when legislation shall be brought to the test of these, and entirely abstracted from partisanship, there will not be very much further legislation to be performed. All questions now undecided, which still remain before the people, such as those of finance, commerce, revenue,

internal improvements, and international policy, should have the touchstone of these principles applied, and they should be decided thereby. It should be asked of them, What course do you point out which will be consistent with freedom, which shall not interfere with equality, and which shall be just to everybody? We venture to assert that, tried by these tests, not a single line of policy which is now being pursued by the Government will stand. Surely its financial policy cannot; for what is there in it which is consistent with the constitutional question of freedom? Surely its revenue, its tariff system, cannot, for what is there in either which is not in direct antagonism with equality?—while we may look in vain for even the skeleton of justice wherever money can find its way.

All this is true, and very much more, and it comes of the departure of legislation and administration from the fundamental propositions of the Constitution. It is also true that such conditions cannot last. The people, as a whole, are not entirely unregenerate, though so many of their self-appointed leaders are. It only remains for the people to become fully aroused to the depths of corruption to which legislation and administration have been carried to demand and obtain the needed redress. This corruption is not confined to Government, but it has permeated nearly all corporate organizations, many of which are organized specially to defraud the productive classes of their hard-earned wealth. The possibility of this being done is because our system of finance is entirely wrong, and nothing will save the country from general financial and commercial ruin except complete revolution in this system. If the ruin comes it will ultimately fall upon the producing classes. In other words, the producing interests of the country cannot sustain the inflation of prices which has been brought about by speculation, in alliance with fraud, which are the ruling spirits of the day.

It may be said that such radical changes as will depose the powers which rule us, and inaugurate the reign of principles, which will secure freedom, equality and justice to every power, cannot yet be introduced. We aver that they can; and further, we aver that unless it is done, revolution such as has never yet been known will inaugurate them for us. The whole substrata of society is seething and foaming with pent-up endurance of injustice and wrong, and unless those abuses which have produced this condition are remedied at once, the existence of the Government cannot be counted upon. And it is criminal to seek to ignore this fact. We must not “lie supinely upon our backs while the enemy binds us hand and foot,” and delivers us to destruction.

In view, then, of our destiny as a nation, and in view of the position which the order of events seems to have assigned us, we are called upon to put our Government in perfect order before the constructive part of the work of the third part of the order of civilization is to be begun. We must be perfect within ourselves before we can expect to become the pattern for others, or expect that others will gravitate to us. THE REVIEW OF THE GENERAL SITUATION, then, results in the finding that the process of diffusive government has culminated, and that the process of a continuously constructive and concentrating government has already been begun, in which our Government, as the most progressive representative of the principles upon which a perfect government can alone exist, is assigned the leading position, and that we, recognizing this assignment, should proceed to assume the responsibilities and the duties which legitimately flow from it; and they are great in the same degree that our destiny is great.

It was under the realization of what our destiny should be that the Pronunciamento of April 2, 1870, in the New York _Herald_, was made; and now, having offered this general review, my Second Pronunciamento, which is supplementary to and the completing of the first, is laid before the people. It is believed that the policy and principles underlying it, proclaimed therein, will be the final departure necessary to be made, as the point from which progress will be continued, until the grand realization of the prophecies of all ages is fulfilled, when all nations, kindred and tongues shall be united in one harmonious family, they having risen into the full knowledge of the truth, that whether we be Christian or Pagan, Greek or Roman, Atheist or Spiritualist, we are all the children of one common Father, God, whom we shall ever worship as the Creator, Ruler and Final Destiny of the Universe.

SECOND PRONUNCIAMENTO.

CONSTITUTIONAL EQUALITY THE LOGICAL RESULT OF THE XIV. AND XV. AMENDMENTS, WHICH NOT ONLY DECLARE WHO ARE CITIZENS, BUT ALSO DEFINE THEIR RIGHTS, ONE OF WHICH IS THE RIGHT TO VOTE, WITHOUT REGARD TO SEX, BOTH SEXES BEING INCLUDED IN THE MORE COMPREHENSIVE PROHIBITORY TERMS OF RACE AND COLOR.

THE STATE LAWS WHICH PROSCRIBED WOMEN AS VOTERS WERE REPEALED BY THE STATES WHEN THEY RATIFIED SAID AMENDMENTS—THERE ARE NO EXISTING OPERATIVE LAWS WHICH PROSCRIBE THE RIGHT OF ANY CITIZEN TO VOTE—THE PERFECTED FRUITS OF THE LATE WAR—THE GOVERNMENT OF THE UNITED STATES IS BOUND TO PROTECT ITS CITIZENS, MALE AND FEMALE, IN THE EXERCISE OF THEIR RIGHT TO VOTE—THE DUTY OF CONGRESS IN THE PREMISES.

The time has now arrived when it becomes proper to present the final and unanswerable proposition, which cannot by any possibility be controverted, that the several States which, until recently, assumed and exercised the right of defining which of its citizens should exercise the right to vote, have by their own voluntary act not only forever repealed all such prohibitory laws, but also have forever barred their re-enactment.

Of this I have been fully aware since the proclamation by the President that the XV. Amendment had become a part of the Organic Law of the country.

To bring the whole matter properly before the public I published an address on the 2d of April last, in which I announced myself a candidate for the Presidency in 1872, and thus asserted the right of woman to occupy the highest office in the gift of the people.

After that address had had its legitimate effect in arousing the press of the country to the realization that women are a constituent part of the body politic, and to a discussion in a much more general way than had ever been before, I published my second address to the people, announcing that the XVI. Amendment was a dead letter, and that the Constitution fully recognized the equality of all citizens.

In this address the general bearings of the Constitution were examined, and from the blending of its various parts the conclusion was arrived at that no State should deny the right to vote to any citizen.

I now take the final step, and show that the States themselves, by their legislative enactments, have removed the only obstacle which until then had prevented women from voting, and have forever debarred themselves from receding to their former position. It is as follows:

SUFFRAGE, or the right to vote, is declared by the XV. Article of Amendments to the Constitution to be a RIGHT, not a privilege, of citizens of the United States.

A right of a citizen is inherent in the individual, of which he cannot be deprived by any law of any State.

A privilege may be conferred upon the citizen of the State, and by it may be taken away. This distinction is made to show that _to vote is not a privilege_ conferred by a State upon its citizens, but a CONSTITUTIONAL RIGHT of every citizen of the United States, of which they cannot be deprived. The language of the Constitution is most singularly emphatic upon this point. It is as follows:

ARTICLE XV.

1. _The right of citizens of the United States to vote shall not be denied or abridged by the United States or by any State on account of race, color, or previous condition of servitude._

It is thus forever proclaimed, in unmistakable terms, that _to vote is a right_ of citizens of the United States.

Were it an immunity, or even were it a privilege, to vote, those who possess it could not be deprived of it by any State, for the State is bound to protect every citizen within its jurisdiction in the exercise thereof. It being declared by the XV. Amendment that citizens of the United States have the right to vote, the next step to determine is, Who are citizens? This is also definitely, though for the first time, determined by Article XIV. of Amendments to the Constitution as follows:

ARTICLE XIV.

1. All persons born or naturalized in the United States, and subject to the jurisdiction thereof, are citizens of the United States and of the State wherein they reside. _No State shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States._ Nor shall any State deprive any person of life, liberty or property without due process of law, _nor deny to any person_ within its jurisdiction the equal protection of the laws.

The next point of inquiry is, How is it that the State laws which formerly did proscribe women and exclude them from the exercise of suffrage, no longer _do_ so? Simply and effectively by this fact, that, by the adoption of the XV. Article of Amendments to the Constitution, the States established, as the “SUPREME LAW OF THE LAND,” the fact that no person born or naturalized in the United States, and subject to the jurisdiction thereof shall be denied or abridged by the United States, or by any State, of the RIGHT TO VOTE.

Women are citizens of the United States; and the States themselves, by their own voluntary act, have established the fact of their citizenship, and confirmed their right to vote, which, by such action, has become the supreme law of the land, which supersedes, annuls and abrogates all previous State laws inconsistent therewith or contravening the same. The XV. Article of Amendments to the Constitution is as much a part of it as any originally adopted; for Art VI., ¶ 2, says:

This Constitution, and the laws of the United States which shall be made in pursuance thereof, and all treaties made, or which shall be made under the authority of the United States, _shall be_ THE SUPREME _law of_ THE LAND; and the _judges in_ EVERY _State shall_ BE BOUND THEREBY; anything in _the Constitution or laws_ OF ANY _State_ TO THE CONTRARY NOTWITHSTANDING.

The XV. Amendment was adopted by the several States as a legislative enactment by their Legislatures, under Art V., which provides:

The Congress, whenever two-thirds of both Houses shall deem it necessary, _shall propose amendments to this Constitution_; or, on the application of the Legislatures of two-thirds of the several States, shall call a convention for proposing amendments, _which_, in either case, _shall be valid to all intents and purposes, as part of this Constitution_, when _ratified by the Legislatures of three-fourths thereof_ as the one or the other mode of ratification may be proposed by Congress, provided that no amendment which may be made prior to the year one thousand eight hundred and eight, shall, in any manner, affect the first and fourth clauses in the ninth section of the first article; AND THAT NO STATE, WITHOUT ITS CONSENT, SHALL BE DEPRIVED OF ITS EQUAL SUFFRAGE IN THE SENATE.

Since, therefore, all citizens have the RIGHT TO VOTE under this act or participation by the Legislatures of the several States, all State Laws which abridge the right are inoperative, null and void, and the exclusion of women who are citizens from the right to vote, was repealed and must stand repealed until the Legislatures of the several States shall again pass an act positively excluding her. If we again examine Art XV. we shall see that this right shall not be denied or abridged by the United States or any State on account of RACE, COLOR, or PREVIOUS CONDITION OF SERVITUDE; it is left to be inferred that it might be on account of SEX, but this denial has not yet been attempted, nor could it be accomplished if it were, for here the XIV. Amendment again comes to our relief saying, “That no State shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States.”

Again, the Constitution is assuredly a contract between States and citizens, and Sec. 10, Art I., provides that no State shall pass any law impairing contracts.

Art I., Sec. 4,¶ I, provides that:

“The times, places and _manner of holding elections_ for senators and representatives shall be prescribed in each State, by the Legislature thereof; but the _Congress may, at any time, by law, make or alter such regulations_, except as to the places of choosing senators,” while the judiciary of the United States has acquired complete jurisdiction over this matter by the authority of Art III., Sec. 2,¶ 1, which provides that: “_The judicial power shall extend to all cases in law and equity arising under this Constitution, the laws of the United States, and treaties made, or which shall be made, under their authority_.”

And for all these reasons, the State Legislatures having, by the adoption of the Fifteenth Amendment, abrogated all previously existing, conflicting laws on the subject of suffrage, are now forever precluded by the Fourteenth Amendment from re-establishing any restriction to apply to women, whom the authorities of the United States, in their support of the Constitution, are in duty bound to protect in their right to vote.

Now what was the fruit of the late war, which threw the entire nation into such convulsive throes, unless it is found in the Fourteenth and Fifteenth Amendments to the Constitution, namely: that grand change in the fundamental laws which declares _who_ are citizens and what are their _rights_, _privileges_ and immunities, which cannot be abridged? Will any one pretend that these great enactments can be understood to mean less than the language thereof plainly conveys? Or will any one claim that the old, absurd State laws, which were sunk in oblivion by the adoption of these amendments to the Constitution, are still in force? Who will _dare_ to say, in the face of these plainly worded amendments, which have such an unmistakable meaning, that the women of America shall not enjoy their emancipation as well as the black slave?

WOMEN HAVE THE RIGHT TO VOTE! It is the duty of the Government to see that they are not denied the right to exercise it, and, to secure the necessary action of Congress in the premises, I did, on the 21st day of December, 1870, memorialize Congress as

recorded in the Congressional _Globe_, December 22, 1870.

In the Senate:

Mr. Harris presented the memorial of Victoria C. Woodhull, praying for the passage of such laws as may be necessary and proper for carrying into execution the right vested by the Constitution in the citizens of the United States to vote without regard to sex; which was referred to the Committee on the Judiciary and ordered to be printed.

In the House:

Mr. Julian—I ask unanimous consent to present at this time and have printed in the _Globe_ the memorial of Victoria C. Woodhull, claiming the right of suffrage under the XIV. and XV. Articles of Amendments to the Constitution of the United States, and asking for the enactment of the necessary and appropriate legislation to guarantee the exercise of that right to the women of the United States. I also ask that the petition be referred to the Committee on the Judiciary.

No objection was made, and it was ordered accordingly.

The petition is as follows:

THE MEMORIAL OF VICTORIA C. WOODHULL,

To the Honorable the Senate and House of Representatives of the United States in Congress assembled, respectfully showeth:

That she was born in the State of Ohio, and is above the age of twenty-one years; that she has resided in the State of New York during the past three years; that she is still a resident thereof, and that she is a citizen of the United States, as declared by the XIV. Article of Amendments to the Constitution of the United States.

That since the adoption of the XV. Article of Amendments to the Constitution, neither the State of New York nor any other State, nor any Territory, has passed any law to abridge the right of any citizen of the United States to vote, as established by said article, neither on account of sex or otherwise:

That, nevertheless, the right to vote is denied to women citizens of the United States by the operation of Election Laws in the several States and Territories, which laws were enacted prior to the adoption of the said XV. Article, and which are inconsistent with the Constitution as amended, and, therefore, are void and of no effect; but which, being still enforced by the said States and Territories, render the Constitution inoperative as regards the right of women citizens to vote:

And whereas, Article VI., Section 2, declares “That this Constitution, and the laws of the United States which shall be made in pursuance thereof, and all treaties made, or which shall be made, under the authority of the United States, shall be the supreme law of the land; and all judges in every State shall be bound thereby, anything in the Constitution and laws of any State to the contrary notwithstanding:” And whereas, no distinction between citizens is made in the Constitution of the United States on account of sex; but the XV. Article of Amendments to it provides that “No State shall make or enforce any law which shall abridge the privileges and immunities of citizens of the United States, nor deny to any person within its jurisdiction the equal protection of the laws:”

And whereas, Congress has power to make laws which shall be necessary and proper for carrying into execution all powers vested by the Constitution in the Government of the United States; and to make or alter all regulations in relation to holding elections for senators or representatives, and especially to enforce, by appropriate legislation, the provisions of the said XIV. Article:

And whereas, the continuance of the enforcement of said local election laws, denying and abridging the Right of Citizens to Vote on account of sex, is a grievance to your memorialist and to various other persons, citizens of the United States, being women,—

Therefore, your memorialist would most respectfully petition your Honorable Bodies to make such laws as in the wisdom of Congress shall be necessary and proper for carrying into execution the right vested by the Constitution in the citizens of the United States to vote, without regard to sex.

And your memorialist will ever pray.

VICTORIA C. WOODHULL.

Dated NEW YORK CITY, _December 19, 1870_.

This memorial having been referred to the Judiciary Committee, I then prepared and submitted the following legal deductions in support thereof:

CONSTITUTIONAL EQUALITY.

TO THE HON. THE JUDICIARY COMMITTEES OF THE SENATE AND THE HOUSE OF REPRESENTATIVES OF THE CONGRESS OF THE UNITED STATES:

The undersigned, VICTORIA C. WOODHULL, having most respectfully memorialized Congress for the passage of such laws as in its wisdom shall seem necessary and proper to carry into effect the rights vested by the Constitution of the United States in the citizens to vote, without regard to sex, begs leave to submit to your honorable body the following in favor of her prayer in said Memorial which has been referred to your Committee:

The public law of the world is founded upon the conceded fact that sovereignty cannot be forfeited or renounced. The sovereign power of this country is perpetual in the politically-organized people of the United States, and can neither be relinquished nor abandoned by any portion of them. The people in this Republic who confer sovereignty are its citizens: in a monarchy the people are the subjects of sovereignty. All citizens of a republic by rightful act or implication confer sovereign power. All people of a monarchy are subjects who exist under its supreme shield and enjoy its immunities.

The subject of a monarch takes municipal immunities from the sovereign as a gracious favor; but the woman citizen of this country has the inalienable “sovereign” right of self-government in _her own proper person_. Those who look upon woman’s status by the dim light of the common law, which unfolded itself under the feudal and military institutions that establish right upon physical power, cannot find any analogy in the status of the woman citizen of this country, _where the broad sunshine of our Constitution has enfranchised all_.

As sovereignty cannot be forfeited, relinquished or abandoned, those from whom it flows—the citizens—are equal in conferring the power, and should be equal in the enjoyment of its benefits and in the exercise of its rights and privileges.

One portion of citizens have no power to deprive another portion of rights and privileges such as are possessed and exercised by themselves. The male citizen has no more right to deprive the female citizen of the free, public, political expression of opinion than the female citizen has to deprive the male citizen thereof.

The sovereign will of the people is expressed in our written Constitution, which is the supreme law of the land. The Constitution makes no distinction of sex. The Constitution defines a woman born or naturalized in the United States, and subject to the jurisdiction thereof, to be a citizen. It recognizes the right of citizens to vote. It declares that the right of citizens of the United States to vote shall not be denied or abridged by the United States or by any State on account of “race, color or previous condition of servitude.”

Women, white and black, belong to races; although to different races. A race of people comprises all the people, male and female. The right to vote cannot be denied on account of race. All people included in the term race have the right to vote, unless otherwise prohibited.

Women of all races are white, black or some intermediate color. Color comprises all people, of all races and both sexes. The right to vote cannot be denied on account of color. All people included in the term color have the right to vote unless otherwise prohibited.

With the right to vote sex has nothing to do. Race and color include all people of both sexes. All people of both sexes have the right to vote, unless prohibited by special limiting terms less comprehensive than race or color. No such limiting terms exist in the Constitution.

Women, white and black, have from time immemorial groaned under what is properly termed in the Constitution “previous condition of servitude.”

Women are the equals of men before the law, and are equal in all their rights as citizens.

Women are debarred from voting in some parts of the United States, although they are allowed to exercise that right elsewhere.

Women were formerly permitted to vote in places where they are now debarred therefrom.

The Naturalization Laws of the United States expressly provide for the naturalization of women.

But the right to vote has only lately been distinctly declared by the Constitution to be inalienable, under three distinct conditions—in all of which woman is distinctly embraced.

The citizen who is taxed should also have a voice in the subject matter of taxation. “No taxation without representation” is a right which was fundamentally established at the very birth of our country’s independence; and by what ethics does any free government impose taxes on women without giving them a voice upon the subject or a participation in the public declaration as to how and by whom these taxes shall be applied for common public use?

Women are free to own and to control property, separate and apart from males, and they are held responsible in their own proper persons, in every particular, as well as men, in and out of court.

Women have the same inalienable right to life, liberty and the _pursuit of_ happiness that men have. Why have they not this right politically, as well as men?

Women constitute a majority of the people of this country—they hold vast portions of the nation’s wealth and pay a proportionate share of the taxes. They are intrusted with the most holy duties and the most vital responsibilities of society; they bear, rear and educate men; they train and mould their characters; they inspire the noblest impulses in men; they often hold the accumulated fortunes of a man’s life for the safety of the family and as guardians of the infants, and yet they are debarred from uttering any opinion, by public vote, as to the management by public servants of these interests; they are the secret counsellors, the best advisers, the most devoted aids in the most trying periods of men’s lives, and yet men shrink from trusting them in the common questions of ordinary politics. Men trust women in the market, in the shop, on the highway and the railroad, and in all other public places and assemblies, but when they propose to carry a slip of paper with a name upon it to the polls, they fear them. Nevertheless, as citizens women have the right to vote; they are part and parcel of that great element in which the sovereign power of the land had birth: and it is by usurpation only that men debar them from their right to vote. The American nation, in its march onward and upward, cannot publicly choke the intellectual and political activity of half its citizens by narrow statutes. The will of the entire people is the true basis of republican government, and a free expression of that will by the public vote of all citizens, without distinctions of race, color, occupation or sex, is the only means by which that will can be ascertained. As the world has advanced in civilization and culture; as mind has risen in its dominion over matter; as the principle of justice and moral right has gained sway, and merely physically organized power has yielded thereto; as the might of right has supplanted the right of might, so have the rights of women become more fully recognized, and that recognition is the result of the development of the minds of men, which through the ages she has polished, and thereby heightened the lustre of civilization.

It was reserved for our great country to recognize by constitutional enactment that political equality of all citizens which religion, affection, and common sense should have long since accorded; it was reserved for America to sweep away the mist of prejudice and ignorance, and that chivalric condescension of a darker age, for in the language of Holy Writ, “The night is far spent, the day is at hand, let us therefore cast off the work of darkness, and let us put on the armor of light. Let us walk honestly as in the day.”

It may be argued against the proposition that there still remains upon the statute books of some States the word “male” to an exclusion, but as the Constitution in its paramount character can only be read by the light of the established principle, _ita lex Scripta est_; and as the subject of sex is not mentioned and the Constitution is not limited either in terms or by necessary implication in the general rights of citizens to vote, this right cannot be limited on account of anything in the spirit of inferior or previous enactments upon a subject which is not mentioned in the supreme law. A different construction would destroy a vested right in a portion of the citizens, and this no legislature has a right to do without compensation, and nothing can compensate a citizen for the loss of his or her suffrage—its value is equal to the value of life. Neither can it be presumed that women are to be kept from the polls as a mere police regulation: it is to be hoped, at least, that police regulations in their case need not be very active. The effect of the amendments to the Constitution must be to annul the power over this subject in the States whether past, present or future, which is contrary to the amendments. The amendments would even arrest the action of the Supreme Court in cases pending before it prior to their adoption, and operate as an absolute prohibition to the exercise of any other jurisdiction than merely to dismiss the suit.

3 Dall., 382; 6 Wheaton, 405; 9 Id., 868; 3d Circ., Pa., 1832.

And if the restrictions contained in the Constitution as to color, race or servitude, were designed to limit the State governments in reference to their own citizens, and were intended to operate also as restrictions on the Federal power, and to prevent interference with the rights of the State and its citizens, how then can the State restrict citizens of the United States in the exercise of rights not mentioned in any restrictive clause in reference to actions on the part of those citizens having reference solely to the necessary functions of the General Government, such as the election of representatives and senators to Congress, whose election the Constitution expressly gives Congress the power to regulate?

S. C., 1847: Fox vs. Ohio, 5 Howard, 410.

Your memorialist complains of the existence of State Laws, and prays Congress, by appropriate legislation, to declare them, as they are, annulled, and to give vitality to the Constitution under its power to make and alter the regulations of the States contravening the same.

It may be urged in opposition that the Courts have power, and should declare upon this subject.

The Supreme Court has the power, and it would be its duty so to declare the law; but the Court will not do so unless a determination of such point as shall arise make it necessary to the determination of a controversy, and hence a case must be presented in which there can be no rational doubt. All this would subject the aggrieved parties to much dilatory, expensive and needless litigation, which your memorialist prays your Honorable Body to dispense with by appropriate legislation, as there can be no purpose in special arguments “ad inconvenienti,” enlarging or contracting the import of the language of the Constitution.

Therefore, Believing firmly in the right of citizens to freely approach those in whose hands their destiny is placed, under the Providence of God, your memorialist has frankly, but humbly, appealed to you, and prays that the wisdom of Congress may be moved to action in this matter for the benefit and the increased happiness of our beloved country.

Most respectfully submitted, VICTORIA C. WOODHULL.

Dated NEW YORK, January 2, 1871.

The issue upon the question of female suffrage being thus definitely and clearly set forth, and its rights inalienably vested in woman, a brighter future dawns upon the country. When Congress shall have moved in the matter, and thus secured to woman the free exercise of these newly-defined rights, she can unite in purifying the elements of political strife—in restoring the Government to pristine integrity, strength and vigor. To do this, many reforms become of absolute necessity. Prominent among these are—

A reform in representation by which all Legislative Bodies and the Presidential Electoral College shall be so elected that minorities as well as majorities shall have direct representation.

A complete reform in Executive and Departmental conduct, by which the President and the Secretaries of the United States, and the Governors and State Officers shall be forced to recognize that they are the servants of the people, appointed to attend to the business of the people, and not for the purpose of perpetuating their official positions, or of securing the plunder of public trusts for the enrichment of their political adherents and supporters.

A reform in the tenure of office, by which the Presidency shall be limited to one term, with a retiring life pension, and a permanent seat in the Federal Senate, where his Presidential experience may become serviceable to the nation, and on the dignity and life emolument of Presidential Senator he shall be placed above all other political position, and be excluded from all professional pursuits.

A radical reform in our Civil Service, by which the Government, in its executive capacity, shall at all times secure faithful and efficient officers, and the people trustworthy servants, whose appointment shall be entirely removed from, and be made independent of, the influence and control of the legislative branch of the Government, and who shall be removed for “cause” only, and who shall be held strictly to frequent public accounting to superiors for all their official transactions, which shall forever dispose of the corrupt practices induced by the allurements of the motto of present political parties, that “to the victor belong the spoils,” which is a remnant of arbitrarily assumed authority, unworthy of a government emanating from the whole people.

A reform in our systems of finance, by which the arbitrary standard of ancient and feudal despotisms shall be removed; by which the true source of wealth shall become the basis and the security of a national currency, which shall be made convertible into a National Bond bearing such an interest, while in the hands of the people, as shall secure an equilibrium between the demands of all

the varieties of exchanges and the supply of money to effect them with, the Bond being also convertible at pleasure into money again, by which system of adjustment, “plethora” equally with “tightness” shall be banished from the financial centres of our country; and which, in its practical workings, shall secure such pecuniary equality between the employing and the laboring classes as will forever make poverty and its long list of consequent ills impossible in our country; and which shall suggest the solution of those schemes which are being discussed for “funding the public debt” at a lower rate of interest.

A complete reform in our system of Internal improvements, which connect and bind together the several States in commercial unity, to the end that they shall be conducted so as to administer to the best interests of the whole people, for whose benefit they were first permitted, and are now protected; by which the General Government, in the use of its postal powers, and in the exercise of its duties in regulating commerce between the States, shall secure the transportation of passengers, merchandise and the mails, from one extremity of the country to the opposite, and throughout its whole area, at the actual cost of maintaining such improvements, plus legitimate interest upon their original cost of construction, thus converting them into public benefits, instead of their remaining, as now, hereditary taxes upon the industries of the country, by which, if continued, a few favored individuals are likely to become the actual rulers of the country.

A complete reform in commercial and navigation laws, by which American built or purchased ships and American seamen shall be practically protected by the admission of all that is required for construction of the first, or the use and maintenance of either, free in bond or on board.

A reform in the relations of the employer and employed, by which shall be secured the practice of the great natural law, of one-third of time to labor, one-third to recreation and one-third to rest, that by this, intellectual improvement and physical development may go on to that perfection which the Almighty Creator designed.

A reform in the principles of protection and revenue, by which the largest home and foreign demand shall be created and sustained for products of American industry of every kind; by which this industry shall be freed from the ruinous effects consequent upon frequent changes in these systems; by which shall be secured that constant employment to workingmen and workingwomen throughout the country which will maintain them upon an equality in all kinds and classes of industry; by which a continuous prosperity—which, if not so marked by rapid accumulation, shall possess the merit of permanency—will be secured to all, which in due time will reduce the cost of all products to a minimum value; by which the laboring poor shall be relieved of the onerous tax, now indirectly imposed upon them by government; by which the burden of governmental support shall be placed where it properly belongs, and by which an unlimited national wealth will gradually accumulate, the ratio of taxation upon which will become so insignificant in amount as to be no burden to the people.

A reform by which the power of legislative bodies to levy taxes shall be limited to the actual necessities of the legitimate functions of government in its protection of the rights of persons, property and nationality; and by which they shall be deprived of the power to exempt any property from taxation; or to make any distinctions directly or indirectly among citizens in taxation for the support of government; or to give or loan the public property or credit to individuals or corporations to promote any enterprise whatever.

A reform in the system of criminal jurisprudence, by which the death penalty shall no longer be inflicted—by which the hardened criminal shall have no human chance of being let loose to harass society until the term of the sentence, whatever that may be, shall have expired, and by which, during that term, the entire prison employment shall be for—and the product thereof be faithfully paid over to—the support of the criminal’s family; and by which our so-called prisons shall be virtually transformed into vast reformatory workshops, from which the unfortunate may emerge to be useful members of society, instead of the alienated citizens they now are.

The institution of such supervisory control and surveillance over the now low orders of society as shall compel them to industry, and provide for the helpless, and thus banish those institutions of pauperism and beggary which are fastening upon the vitals of society, and are so prolific of crime and suffering in certain communities.

The organization of a general system of national education, which shall positively secure to every child of the country such an education in the arts, sciences and general knowledge as will render them profitable and useful members of society, and the entire proceeds of the public domain should be religiously devoted to this end.

Such change in our general foreign policy as shall plainly indicate that we realize and appreciate the important position which has been assigned us as a nation by the common order of civilization; which shall indicate our supreme faith in that form of government

which emanates from, and is supported by, the whole people, and that such government must eventually be uniform throughout the world; which shall also have in view the establishment of a Grand International Tribunal, to which all disputes of peoples and nations shall be referred for final arbitration and settlement, without appeal to arms; said Tribunal maintaining only such an International army and navy as would be necessary to enforce its decrees, and thus secure the return of the 15,000,000 of men who now compose the standing armies of the world, to industrial and productive pursuits.

Thus in the best sense do I claim to be the friend and exponent of the most complete equality to which humanity can attain; of the broadest individual freedom compatible with the public good, and that supreme justice which shall know no distinction among citizens upon any ground whatever, in the administration and the execution of the laws; and also, to be a faithful worker in the cause of human advancement; and especially to be the co-laborer with those who strive to better the condition of the poor and friendless; to secure to the great mass of working people the just reward of their toil,—I claim from these, and from all others in the social scale, that support in the bold political course I have taken, which shall give me the strength and the position to carry out these needed reforms, which shall secure to them, in return, the blessings which the Creator designed the human race should enjoy.

If I obtain this support, woman's strength and woman's will, with God's support, if He vouchsafe it, shall open to them, and to this country, a new career of greatness in the race of nations, which can only be secured by that fearless course of truth from which the nations of the earth, under despotic male governments, have so far departed.

VICTORIA C. WOODHULL.

NEW YORK, JANUARY 10, 1871.

TENDENCIES OF GOVERNMENT.

[Revised from the New York Herald of April 16, 1870.]

VICTORIA C. WOODHULL ON THE "TENDENCIES OF GOVERNMENT."

GOD IN CREATION, IN HISTORY, AND IN GOVERNMENT—A PHILOSOPHICAL PREFACE TO A PHILOSOPHICAL DISCOURSE.

[The head of the firm of Woodhull, Claflin & Co., Commodore Vanderbilt's financial _proteges_—the famous brokers of Broad street—has undertaken the difficult task of correcting popular errors in the science of government, and has prepared a paper on the subject, which, as the lady expects to be too busy to deliver for some time to come, we publish it _in extenso_. Whether her conclusions will agree with her premises or not, the document will be found exceedingly interesting, as showing the quality of the female mind against which the money changers of Wall street will have to contend in business:]

As far back into the past as dim historic lights enable us to see, and still much farther, even behind the appearance of man upon the face of this planet, the existence of government can be plainly traced. Wherever two or more of any species of animals—not to descend lower and including man—are or have been, something simulating to what is in our day denominated government exists or existed; and, whether it is or was over a greater or less community, it is or was possessed of certain characterizing elements, from and by which a clear insight into the composition of the community can be obtained by those who will analyze the elements somewhat philosophically; that is to say governments are truthful reflections of the governed when considered as a whole, and all changes or modifications that occur therein, result from growth of the governed.

No just nor advantageous deductions from any subject or fact which is worthy of a position in the world's history, and which is capable of permanently maintaining such a position, can be arrived at, except through a complete philosophical analysis of all the elements entering into its composition. All facts as well as all chemical compounds are made up of elementary principles brought into intimate productive relations by some general power, operating by some general law of combination. By such an analysis the composition of such subjects and facts as are analyzed are not only determined, but the relations which they sustain to all other subjects and facts are also demonstrated, and thus a general law of relativity is found which makes the whole round of creation one in purpose and effect.

It is not proposed in the present article to prosecute an exhaustive analysis of government as it is or as it has been, but rather to observe the chain of progression which has been evolved, and to endeavor to determine whether, link by link, it does not form one

harmonious whole, from the present aspect of which its culmination may be caught sight of; and whether that culmination will not be found a complete circle, containing within its immense area all that has conspired and assisted in its completion, and which will be entitled to positions in such a community of interests by virtue of having thus conspired and assisted in its formation.

Neither is it proposed to extend the limits of this inquiry beyond the consideration of human government, except in so far as analogies may be sought to enforce the application of general laws and to assist by such application in the solution of such questions as may not be entirely apparent from the evidences contained specifically within the said limits. Philosophically considered, however, the objects sought could as well be obtained from any other department of government; for, while a general law underlies all forms and systems of human government and controls all its modifications, the self-same law underlies and controls all other forms and systems of government, from which human government sprung and upon which it rests as a primary basis.

It is believed that there is sufficient mental development and comprehension contained in the philosophic minds of this latter part of the nineteenth century to gather into form the evidence that has been and is being presented, in the evolution and dissolution of government, and grasp its signification, so that in its application to existing things, permanent instead of politic modifications in governmental affairs may be inaugurated. Governed by any other than such a broad standard, changes and modifications in present systems and forms are made simply to meet the exigencies of the times, and with no view to place government upon a basis which should never need modification, and which should meet all exigencies of all times. The reasons why such government has not hitherto been inaugurated or attempted, are, because in no country has the general mind as yet become sufficiently broad and comprehensive to discover that great general laws underlie the universe and govern all its manifestations, applying to each and every department thereof with perfect uniformity. It is not my province to discuss what these great general laws and principles are. I assume that they do exist, and it is my office to predicate what the future of government must be when it shall have its basis in such laws and principles, and to judge whether what has been, and what is, may be considered as gradual approaches from the most simple and homogeneous forms in which the interest of all were very indefinite, either individually or collectively, toward that wherein the interests of all, while becoming more distinct individually, shall be merged in the general interests of the whole and become identical therewith.

Mr. Maine says, in his “Ancient Law,” that “society in ancient times was not what it is assumed to be at present—a collection of individuals. In fact, and in view of the men that composed it, it was an aggregation of families. The contrast may be best and most forcibly expressed by saying that the unit of an ancient society was the family; of a modern society, the individual.”

In speaking of ancient society, Mr. Fiske says: “Family government excluded not only individual independence but also State supremacy; and that vestiges of a time when there were no aggregates of men more extensive than the family may be found in every part of the world, when social organization was but one step removed from absolute and ferocious anarchy;” and this he defines as a social aggregate of the first order; the coalescence of families into civic communities an aggregate of the second order; the coalescence of civic and tribual communities into the nation an aggregate of the third order. The coalescence of nations would then describe an aggregate of the fourth order. Under these four orders all the forms of government which can ever exist in the world must be classified.

As low a form of government as can be conceived as existing next above that of the family, worthy to be called human government, still exists among the barbarians inhabiting some portions of Central Africa, some of the East India Islands, and perhaps some of the South Sea Islands. These people unite in bands or tribes, and rove about seeking the means of subsistence and endeavoring to conquer other tribes. Some have central points of rendezvous, where the rudest habitations are constructed, in which the women and children remain during the absence of the men. The women almost universally are considered very much in the light of slaves by all these nomadic tribes, and as only fit to minister to their passions and to perform their drudgery. Their language is as rude as their habits, consisting of little more than a comparatively few spasmodically uttered harsh sounds. Written language they have none, excepting perhaps some images or rude figures symbolizing some special event they in this way attempt to commemorate, and which may be considered as the foundation of it for the tribes using them as they were the primary foundation of all written language.

One notable feature is universally observable among all these representatives of primitive government—they all recognize the necessity of a leader under some of the many forms of control exercised by the one over the many, and he is generally one who has exhibited some particular prowess in battle, the capacity to perform which he is supposed to be endowed with by some unknown power, and which renders him superior to all others, and best capable of ruling and protecting those who thus recognize

him, and who obey him in every particular, even to sacrificing their lives. Such may be considered an outline of our conceptions of the most primitive form of government of the present day; and the fact that such still exists has a marked bearing upon the subject of general government, when it is remembered that the time was when no higher form existed on the face of the earth.

The law of evolution and that of dissolution being a universal deduction from the philosophic ultimatum _that force persists_, they apply to all things wherein force is exhibited; consequently human government must be the objective result of the persistence of force exhibited among the people of the earth, and at the same time the subject of all modifications that grow out of its transformations and equivalent relations. In whatever light, then, human government is viewed, these philosophic laws should never be lost sight of nor disregarded; but the causes of all the rises and falls, transformations, modifications and amalgamations, should be sought by the application of those laws to the objective points under consideration.

The question now naturally arises, Can human government, then be analyzed, and the facts it presents be found to correspond to the deductions of philosophic law?

It has been remarked that the simplest combinations of force among human beings, representing government which existed when none higher had been attained, was still represented on the earth by certain of its inhabitants. Beginning with this as the basis of the superstructure of human government, can there be traced a gradual scale of progress from it to the government of this country, in which scale each nation, tribe and tongue will find its appropriate place, which, unoccupied, would render the scale imperfect, as a chain would be imperfect were one of its central links missing? and would an analysis of each of these governments develop the fact that each successive one in the progressive scale would represent some new application of the principle of liberty, some more extended idea of equality, or some better formula of justice than the preceding had, which application, idea or formula entitles it to rank superior thereto, and also determines its position in the scale?

Of all systems and forms of government that came and passed away during the long lapse of ages, from the time the most primitive alone existed on the earth to the time wherein those flourished that have left records of their existence, we can know nothing except what may be gathered from philosophic deduction unsupported by any actual record of facts concerning them. It is, however, philosophically certain that very many such intermediate governments did exist, variously modified and advancing from the primitive forms. Possessing, as we may justly infer, but little capability for duration, their integration was rapidly succeeded by disintegration; being exposed to numerous and different external influences, rapid and successive changes were inevitable, because they were possessed of but little individuality and consequently but little capacity for resisting external influences. They were bound together by none of the higher laws of association, but were led by transient ephemeral contingencies, combining at times together, to soon divide and subdivide only to again form new and equally temporary amalgamations. Thus constantly organizing and dissolving, the long interval alluded to was occupied by primitive inhabitants in their march from the purely homogeneous toward the individualized times wherein civilization left records of itself.

While no special inquiries into the correctness of the formulas laid down at various times by various philosophers, which seek to include and cover all the phenomena of the universe, will be made, those of the most eminent may with propriety be stated; indeed, if it be attempted to show that history obeys a fixed law of evolution, the law that it is presumed to obey must be given, that it may be seen whether the deductions arrived at are included within the limits of the formula. If it should not so turn out, then either the deduction must be illegitimate, the formula imperfect or impossible, or the fact made apparent, that, while all the other sciences, as biology, psychology and their various divisions, are known to conform to certain well determined laws of causation, sociology, in which all history and government find their basis, conforms to no law, but is the product of the merest chance.

Until within the present century it was not claimed by any of the various philosophers who had flourished that there was such a science as sociology; or, if so claimed by any far-seeing mind, the attempt to demonstrate or formulate it was not made until the time of Comte, who, about the year 1830, did attempt it, and he may be justly styled the father of the present system of formulated science. Though his system is now shown to contain many imperfections and omissions, it is nevertheless certain, that but for it, the improvements since made would not have been possible to the present degree attained, though those who have made them may repudiate the idea, and scorn to acknowledge that they have built upon Comte.

Gathering from his profuse writings upon this point his earlier and most continuous opinions, the following are the terms in which they can be the most simply expressed: Social progression is a gradual change from rudimentary, homogeneous and anthropomorphic conditions to civilization, heterogeneity and to definite conceptions of the external world; and at the same time from nomadic characteristics, with aggressive purposes, to inhabitative propensities and individual industrial pursuits.

A number of philosophers, who have written since the days of Comte, have from time to time presented formulas which at best can only be considered as modifications of his, and it may confidently be asserted that no real addition was acquired until the Spencerian was made, which, while it included Comte's, was more general and comprehensive, and at the same time more definite and special. This seeming anomaly was made possible by his having discovered the law of evolution, and by having exhaustively demonstrated that all mental action—emotional as well as intellectual—was included in it. It is as follows: Evolution is an integration of matter and a concomitant dissipation of motion, during which the matter passes from an indefinite, incoherent homogeneity to a definite, coherent heterogeneity, and during which the retained motion undergoes a partial transformation. This general formula includes all evolution, organic and inorganic, and interprets not only the genesis of the sidereal and solar systems and of the earth, but also of life upon the earth, and has become the law of all social, moral and intellectual change. He afterward found it necessary to make a supplement especially applicable to organic life, in such terms as should not include the inorganic. It was as follows: "Life—and intelligence being the highest manifestations of life—consists in the continuous establishment of relations within the organism, in correspondence with relations existing within the environment or the surroundings."

To this exhaustive statement a late generalization and specialization has been made by Mr. Fiske, especially applicable to social evolution, as follows: The progress of society is a continuous establishment of psychical relations within the community, in conformity to physical and psychical relations arising within the environment, during which, both the community and the environment pass from a state of incoherent homogeneity to a state of coherent heterogeneity, and during which the constitutional units of the community become ever more distinctly individuated.

Having now arrived at that point where history must furnish the facts upon which the subject rests, it may be well to comprehensively recapitulate a perhaps somewhat too long introduction. It was seen that all over the face of the earth where human life was represented, government exists, and that this government was representative of one or another of the three orders of aggregates of individuals—the family, the tribal, or the nations, and that an aggregate of nations would add the fourth order. It was also seen that the evolution of government was the objective result of the persistence of force among its component parts. Fixing the basis of government in this philosophic fact, it was necessary to examine the history of government to see if in its evolution it had conformed to this law, according to present accepted formulas; and if so found to have done, to extend the same into the future, to ascertain if possible what the future would be. Thus by a present understanding of the law and its tendencies, all modifications and changes made in present systems and forms might be so made in harmony therewith, and not with a simple view to meet the present exigencies, but with an understanding that would meet all exigencies of all time, which alone is perfect legislation.

THE TENDENCIES OF GOVERNMENT.

[Revised from the New York Herald of April 25, 1870.]

SECOND PART OF MRS. VICTORIA C. WOODHULL'S PHILIPPIC—LAWS, PEOPLES AND COMMUNITIES FROM A FEMALE POINT OF VIEW—LESSONS IN HISTORY, POLITICS AND WAR.

[Mrs. Victoria C. Woodhull, head of the firm of female brokers in Broad street, presents to the readers of the _Herald_ the following communication, the second part of her paper on "The Tendencies of Government," the preface to which has already appeared. Mrs. Woodhull has undertaken the difficult task of enlightening the public mind on the best means of running the Government machine of America. Though her views, expressed in this paper, have a wide range, it must be said that she is but putting herself in wind for a tremendous attack on "the best Government the world ever saw." Being already in the race for the Presidency (not of the Sorosis, but of the United States), her pronunciamentos are of course very important:]

It must begin to be apparent that the proposition is, that the evolution of government does not differ from that of simplest organic forms either in principle or in mode of operation. The same laws that govern the growth and multiply the plant also govern society and multiply it. The same laws that bring fruit to perfection and dissolution perfect and dissolve societies. The same laws that produce and control the units of the animal kingdom produce and control the units of society. The same law that governs the ebbing and flowing of the tides, that determines whether the component parts of water shall exist as water or vapor, determines the movements of society and the conditions of its existence; and the same law that produces an earthquake here, a volcanic eruption there or a terrific hurricane elsewhere, produces the earthquakes, volcanic eruptions and the hurricanes that are ever modifying and changing society. Symbols of all the various processes society passes through in its growth and extension can be found in

every other department of the universe; or, to assert the same fact differently, everywhere in the universe there is a constant effort to attain an equilibrium—a continuous working to supply wants, an unceasing process of demand and supply, which are universal exemplifications of the law that motion is always in the direction of the least resistance or the greatest traction, or the resultant of the two operating conjointly.

But what does history tell of the foundation and dissolution of governments, and what illustrations of the law of progress does it afford? As before stated, those who have most earnestly studied pre-historic time have found ample evidence that the time was when the head of the family was the highest sovereign power, and so absolute in its character that the individual was entirely submerged in it, and State supremacy was an impossibility. Nothing but anarchy and confusion could have attended such rule; constant rivalry, jealousy and contention must have kept up a continual strife between adjacent families, which could know no settlement except through the subjugation or destruction of the weaker of the contending parties. Of this order of governmental aggregations, it is questionable if the earth at present furnishes any illustrations, unless it be in some part thereof to which the discoverer has not yet penetrated. Of the next, or tribal, order of aggregates, it does, however; and with this second order the real analysis and comparison must begin, though we have no objective means of demonstrating the conditions stated as existing. When family sovereignty was universal it can readily be seen that the continued existence of such conditions would be impossible, for the continuous subjugations and amalgamations of families would lead directly to tribal communities, at first in absolute subjection to one tribe, which would grow into some power, distributed among the several tribes. So also would the joining together of several weak families to resist a more powerful neighbor lead directly to confederation.

The subjugation and reduction of families to bondage and slavery was the beginning of that system of interdependence now so broadly extended into commerce, exchange and mutual dependence for almost the necessities of life. In the times referred to every man was his own farmer, tailor, carpenter and cook, and this condition was only modified when the individuals of conquering families began to rely upon the conquered for certain services they otherwise would have been obliged to render themselves. All of these facts exemplify another philosophic proposition—that for anything in the universe to remain in its homogeneous condition is impossible, which impossibility is the result of the fact that motion must produce change, while constant motion is inevitable so long as force persists and matter resists.

That eminent historian of the third decade of the eighteenth century, Rollin, thus remarks of the earliest monuments which are preserved, treating of the progress from simple to complex forms of government:—“To know in what manner the states and kingdoms were founded that have divided the universe, the steps whereby they rose to that pitch of grandeur related in history, by what ties families and cities united in order to constitute one body of society, and to live together under the same laws and common authority, it will be necessary to trace things back in a manner to the infancy of the world and to those ages in which mankind, being dispersed into different regions, began to people the earth.” In these early ages every father was the supreme head of his family; the arbiter and judge of whatever contests and divisions might arise within it; the natural legislator over his little society, the defender and protector of those who, by their birth, education and weakness, were under his protection and safeguard. The laws which the paternal vigilance established in this domestic senate being dictated with no other view than to promote the general welfare, were concerted with such children as were come to years of maturity and accepted by the inferiors with a full and free consent, were religiously kept and preserved in families as an hereditary polity, to which they owed their peace and security.

But different motives gave rise to different laws. One man, overjoyed at the birth of a first born son, resolved to distinguish him from future children by bestowing on him a more considerable share of his possessions, and giving him greater authority in his family. Another, more attentive to the interests of a beloved wife or darling daughter, whom he wanted to settle in the world, thought it incumbent on him to secure her rights and increase her advantages. The solitary and cheerless state a wife might be reduced to in case she should become a widow affected more intimately another man, and made him provide beforehand for the subsistence and comfort of a woman who formed his felicity. In proportion as every family increased by the birth of children and their marrying into other families, they extended their domain, and by insensible degrees formed towns and cities. From these different views and others of a like nature arose the different customs and rights of nations.

These societies growing in time very numerous, and the families, dividing into different branches, each having its head, it was necessary to intrust one person with the whole in order to unite all these heads under one authority and to maintain the public good by a uniform administration. To heighten the lustre of this newly acquired dignity and to cause them to devote themselves entirely to the public good, the title of king was bestowed upon them and they were invested with full power to administer justice and to punish crime.

At first every city had its particular king, who, being more solicitous of preserving his dominion than of enlarging it, confined his ambition within its limits But the unavoidable feuds that break out between neighbors, the jealousy against a more powerful rival, the turbulent spirit of a prince, his martial disposition or thirst for aggrandizing himself and displaying his ability, gave rise to wars which frequently ended in the entire subjugation of the vanquished and the addition of their cities to the victors. Thus a first victory led the way to a second, which, making a prince more powerful and enterprising, several cities and provinces became united under one monarch, forming kingdoms of greater or less extent, according to the degree the victor pushed his conquests. Such was the origin of the famous empires that at times included the greater part of the known world.

From various historical authorities the following summaries of history are obtained, and are presented as containing some of the principal points by which the general progress of the world should be judged. The principal empires of ancient time will be observed separately; those of modern time under one head, because of the more connected character of their histories, and because of the more general knowledge that is possessed of them. Then the general course events took will be noticed, the deductions that legitimately flow from them introduced, and the bearing they have upon present affairs of the world in reference to its future condition of government considered.

There are several nations that have, at various times, and that still do claim, the greatest antiquity. The Chinese, the Indians, the Syrians and Egyptians appear to have the most evidence to support their claim. The Egyptians once accorded it to the Phrygians, through the result of the somewhat singular experiment of confining two children away from all intercourse with the world until they began to cry, "_Beecos_," which was found to be the Phrygian word for bread. This word, Psammetichus, the King decided must be of the original language, and consequently that the Phrygians were the original people.

Manetho, a high priest in Egypt, who had charge of the sacred archives, pretends to have extracted from the writings of Mercurius and to have proved thereby that up to the time of Alexander the Great, whose reign began 356 years B. C., there had been thirty dynasties in Egypt, which together covered a space of more than 5,300 years. If this claim be allowed, Egypt has existed 7,500 years. Herodotus says "that the Egyptian priests computed 341 generations until the reign of Sethon," which began 719 years B. C. "These generations," he adds, "make 11,341 years." They also counted a like number of priests and kings, who had succeeded one another without interruption, under the name of "Pyromas," signifying good and virtuous. These priests hewed 341 colossal statues in wood of these Pyromas, all arranged in a large hall in the order of their succession.

Let these claims be false or true, historians unanimously agree that Menes was the first King of Egypt, and that his reign began 2,188 years B. C., which would make its historic age about 5,000 years; undoubtedly its fabulous age would cover a sufficient period to make what is claimed, at least by Menetho, if not by the priests Herodotus mentions. These claims will seem the more probable when we are informed that a few ages only after Menes, the first King, one Busiris, built the famous city of Thebes, and made it the seat of his empire, which would seem to indicate that the arts and sciences had at that time been carried to a considerable degree of perfection, not only in the building of cities, but also in their adornment; for we are told that the public buildings were decorated with sculptures and paintings of the most exquisite beauty.

Additional force is also given these claims by the fact that Osymandyas, the successor of this Busiris, collected a magnificent library at Thebes, called "The Treasury of Remedies for Diseases of the Soul," which would indicate that polite learning had made considerable advancement as well in philosophy as in religion. Historians also inform us that Cham, the father of Misriam—the same with Menes—was the second son of Noah, and it is supposed that he retired into Africa after the "confusion of tongues." He was doubtless the Jupiter Ammont so long worshiped as a god by the Egyptians. We are also informed that this Cham, or Ham, had three other sons—Chus, who settled Ethiopia; Phut, who settled Africa westward from Egypt, and Canaan in the country that afterward was called after him, and whose descendants were called Phœnicians.

When we remember the so-called flood; that Cham was the second son of Noah and the father of Menes, the first king, 2,189 years B. C., and that 200 years later Osymandyas, one of his successors, was able to fit out an expedition against the Bactrians of Asia, consisting of 400,000 foot and 20,000 horse, it must be conceded that if the "flood" destroyed all the people existing on the face of the earth, except those saved in the ark, the descendants of Cham must have multiplied with inconceivable rapidity to have made the collecting of such an army possible. But this is not more astonishing than the supposition would be that there could be contained in the atmosphere surrounding the earth sufficient moisture to form the amount of water, which, falling through a space of forty days and nights, should cover the whole earth to the depth narrated of Noah's flood; nor more so than that the temperature of the whole earth at that time should have been so uniform as to have permitted rain throughout, instead of hail or snow, in frigid portions thereof. And if we were to inquire where such a quantity of water was borrowed from and returned, a consistent reply

would be equally surprising; for it is now known that there is just as large a quantity of the elements that compose water at present as there was then.

Considerable latitude can be allowed the statements regarding the flood, when it is remembered that the knowledge of geography, astronomy and meteorology must have been exceedingly limited at that time. But if credence is given to it as having occurred—and it is conceded that all the people Noah knew were destroyed by it—and a solution is sought, it can be imagined that a tremendous upheaval of mountains in Northern Asia might have thrown the waters of the Arctic Ocean southward over the country Noah dwelt in; but this could not have been the result of forty days and forty nights rain, though it may have rained continuously during that period, and may have been considered such by Noah.

This digression was not made so much to consider the probabilities of a flood having occurred as to give additional force to the historic fact that but a few generations after it is said to have occurred, immense tribes of people did exist in that portion of the world bordering on the eastern Mediterranean Sea, who were possessed of considerable general knowledge, immense wealth, and, for that age, good ideas of governmental justice; besides these people, it must also be remembered vast hosts of barbarians existed in the more remote parts of Europe, Asia and Africa, of whose origin and condition nothing can be positively known, either of which bodies of people could not have descended from Noah's family through the common course of reproduction.

What concerns this inquiry most, is not whether all or any of the narratives of ancient writers are entitled to credence, but how and in what directions the ancient tribal nations extended themselves and became merged one with another. Following the history of Egypt from the time of Menes through the reigns of his successors—Busiris, Osymandyas (whose mausoleum displayed such extravagant magnificence), and Euchoreus, who built the famous Memphis and made it the key to the Nile—on through the space of two hundred and sixty years of the Shepherd Kings, from Phœnicia to Amosis, who expelled them, and reunited the country, and to Sesostris, the most powerful king and the greatest conqueror the world had then known, but little evidence of increasing proficiency in science and art is found, but much that the acquired standard was continually being extended among the people and among surrounding nations.

With the reign of Sesostris a new era was inaugurated, and a mighty impetus to general civilization, as well as to special advancement, was given by his wisdom and foresight. Amenophis, the father of Sesostris, no doubt feeling the weight of impending events, foresaw the necessity of preparing him to meet them. He not only took great care that his education in the arts and sciences, the principles of government, philosophy and the art of war, should be complete, but also caused all male children of Egypt born the same day he was, to be educated with him, with the distinct understanding that they were to be his future comrades, his officers, ministers and friends in the aggressive wars he intended he should engage in when he should ascend the throne. It is said that the celebrated Mercurius had charge over them all, especially in politics, war and government.

The first war Sesostris engaged in was against the Arabs, which his father sent him upon while yet quite young, that he might acquire practical knowledge in conducting military campaigns. This people, who had never before been subdued, he conquered, and added their country to Egypt The next year he invaded Lybia, a country to the southwest of Egypt. During this expedition his father died, leaving the throne to him. He immediately formed a no less design than of conquering the whole world. This was in 1491 B. C., and he was probably the first of the great conquerors of ancient times who conceived the idea of reducing the world to a single form of government, and most assuredly the first possessed of sufficient wisdom to carry out so gigantic an undertaking. The manner he set about to do this, and the capacity he evinced in all the preparations, we shall have occasion to compare hereafter with that pursued and shown by others in after time, simply remarking here that it is safe to conclude that Sesostris was great among the greatest; for, to boundless ambition—possessed by many—he united the capacity to sustain it, which few can boast. While making the most extensive preparations for raising and disciplining armies for foreign operations, he was not less active in providing for sustaining the dignity and power of his Government during his absence, which he foresaw would give opportunity for rivals to attempt to overthrow for their own benefit. His first army consisted of 600,000 foot, 24,000 horse, and 27,000 armed chariots, and its principal officers were the 1,700 youths who had been educated with him, and who now made it possible for him to secure perfect discipline and the greatest efficiency.

With this army he first invaded and conquered Ethiopia, and made it tributary to Egypt. He next fitted out an expedition of 400 sail, and made himself master of all the islands and coasts of the Red Sea, as a preparatory step to the conquest of Asia, then advanced into Asia, subduing all the countries, even "beyond the Ganges." Returning westward, he conquered Scythia, Armenia, Cappadocia, Colchis, and all Asia Minor: then crossed into Europe, and would probably have subdued all its nations had he not encountered a great scarcity of provisions in Thrace, which caused him to return. Herodotus says that the Egyptian Empire

extended from the Danube even beyond the Ganges, and included all of Africa, and that all over this vast territory there were erected pillars, on which was inscribed “Sesostris, king of kings and lord of lords, subdued this country by the power of his arms;” which, while it displayed a commendable spirit in marking the limits of his conquest, it at the same time evinces a growing personal vanity that afterward seriously tarnished his early fame.

After having thus conquered the then entire known world, Sesostris returned to Egypt with innumerable captives and laden with spoils, and, by devoting himself to enriching and benefiting Egypt, rather than to extending his dominions, fame and grandeur, showed that his ambition had expended itself in his first great campaign. From all that can be gathered of his reign over Egypt, it must be inferred that no country before, if since, was ever more happily disposed toward its sovereign. The many monuments of his greatness, throughout his dominions, were covered with inscriptions, asserting that all Sesostris’ mighty deeds were accomplished without burdening his subjects; but, on the contrary, they all had become able, through them, to pass the remainder of their days in “calm and repose.”

Having subdued so much of the world, had he been equally ambitious to extend over it the same beneficent Government that he held over Egypt—which he could easily have done through the numerous competent persons the foresight of Amenophis had provided him with, who were well versed in his policy and administration of affairs—Sesostris would undoubtedly have earned and been entitled to the appellation of the world’s benefactor. It appears, however, that he did not exert himself at all in this direction, but was content to receive the annual tributes he levied to enrich Egypt proper. His reasons for pursuing this course, rather than of endeavoring to reward his most worthy adherents by making them rulers of the countries they had assisted him to conquer, are incomprehensible, and that they should not have urged him to it equally so. When it is considered how wisely and happily he governed Egypt, it can be imagined how vastly he might have benefited the conquered people by diffusing correct knowledge of the art of government among them through extending his rule over them.

As it was, it came about, that various Egyptian colonies scattered here and there over the conquered country, and in this way were instrumental in spreading the wisdom of their nation. It was one of these colonies that afterward became the famous Athens—the seat of learning, literature and philosophy. It was about this time also that the use of letters was introduced by one Cadmus, whom the Egyptians claimed to be of their country; but the majority of writers agree that they originated in Syria, and that they were identical with the Hebraic. Of these, however, there were but sixteen, four others being added some two hundred and fifty years later, and the remaining four a long time afterward.

The reign of Sesostris may justly be considered as having produced more general and extended influence upon the world than that of any of his ancestors of any country, and that nothing occurred that can hold any degree of comparison to it until the time of Alexander, more than a thousand years afterward. Sesostris was succeeded by Pheron, and he by Proteus, who dedicated the beautiful temple to “Venus the Stranger,” supposed to be “Helen of Troy,” famous for her beauty, and who was stolen by Paris, from whom she was taken by Proteus and returned to the Greeks.

Under succeeding reigns, the glory of Egypt began to decline, violence and cruelty to usurp the places where justice and moderation had so long prevailed, and jealousies, petty malice and personal aggrandizement to take the place of that love of country which is superior to self; nor could aught else have been expected from the ill-advised luxury and ease the country obtained under Sesostris, which should have been converted into action and expended upon tributary nations. The downward tendency, or the disintegrating process, having begun, demonstrated that the principle upon which Egypt rose and flourished had culminated, and was now to be disseminated among other nations and tribes. Nor could any effort of succeeding rulers, who saw the process at work and understood the causes thereof, stop the downward tendency, which continued with but temporary interruptions until the death of Tharaca, 687 years B. C., when the kingdom remained in a state of anarchy, until twelve noblemen conspired to divide it among themselves. For some superstitious reasons Psammetichus, one of the twelve, was banished; but he, entering into a league with some Greeks, made war upon the eleven, defeated them, and again united the kingdom under one rule, and remained sole possessor of it until his death.

Six hundred and sixteen years B. C. one Nechos arose, who attempted the cutting of a canal from the Nile to the Red Sea, but was unsuccessful. This, however, was partly atoned for by the accomplishment of a voyage entirely around the coast of Africa by some skilful Phœnician sailors he employed, they leaving Egypt by the Red Sea and returning by the way of the Mediterranean after an absence of three years. This passage was made some 2,000 years before the Portuguese discovered this way to the Indies, by which these Phœnicians were able to enter the Mediterranean through the Straits of Gibraltar.

Trouble after trouble now distracted the kingdom, and its power and influence declined with every reign, until the Persians, under Cambyses, 525 years B. C., subdued it. Since the downfall of the Persian Empire, Egypt has successively been subject to the Macedonians, Romans, Saracens, Mamelukes, and lastly the Turks, by whom it is now nominally possessed. The late accomplishment of the project Nechos failed in may be prophetic of radical changes in the condition Egypt has so long been submerged in—the indications being favorable for a return to considerable importance among the nations of the earth.

THE TENDENCIES OF GOVERNMENT.

[Revised from the New York Herald of May 2d, 1870.]

MRS. WOODHULL'S THIRD LETTER.

Nearly all historians who have written since Josephus have endeavored to reconcile sacred and profane history. This task Rollin attempts regarding the origin of the Assyrian empire. Diodorus says that "Ninus, the most ancient Assyrian king, performed great actions. Being naturally of a warlike disposition, and ambitious of glory which results from valor, he armed a considerable number of young men that were brave and vigorous, like himself, and trained them to all manner of hardships." This Ninus, Rollin endeavors to make it appear, was the Nimrod of the Scriptures, and the Belus who was afterward worshiped as a god. Calisthenes, a philosopher, who was one of the retinue of Alexander the Great, says the Babylonians reckoned their origin back some 115 years after the Deluge, which would be about 2,250 years B. C. The conflict of authority upon the origin of this empire, renders it competent for our purpose to assume this date, and that Nimrod was the first historic king of Assyria.

* * * * *

Assyria is supposed to have derived its name from Asshur, the son of Shem, who, the Scripture says, settled this country. Nimrod possessed himself of the province, introduced his own subjects into it, built cities and made himself generally beloved. It is said he built Nineveh, more grand and magnificent than all the rest, and named it after his son Ninus, who, on his accession to the throne, conceived the design of extending his conquests, and began to prepare troops and officers capable of carrying it out. In seventeen years he conquered all the country between Egypt, India and Bactriana, which last country he did not think himself strong enough to attack with success.

While preparing for further and greater conquests he also determined to immortalize his name by making of Nineveh a city at once commensurate with his power and wealth. His design, says Diodorus, was "to make it the largest and noblest city in the world, and to put it beyond the power of others who might come after him to ever build another such. Nor," as Rollin adds, "was he deceived in this; for never did any city come up to the greatness and magnificence of this." It was eighteen miles and three-quarters long and eleven miles and one-quarter broad, and was surrounded by a wall one hundred feet high.

Having completed Nineveh he pursued his intended campaign against the Bactrians, into whose country he marched an army of 1,700,000 foot, 200,000 horse and 20,000 chariots, armed with scythes. With this vast array he quickly overran the whole country and finally laid siege to its capital. This city was strongly fortified and stoutly defended, so much so that Ninus began to despair of reducing it, when the wife of one of his officers advised him how to attack its citadels so as to capture them, and by them the city. This woman was the afterward celebrated Semiramis. Ninus made use of her advice, and the city fell into his hands with but little loss to him.

Ninus, finding a woman possessed of such remarkable capacity to aid him in his ambitious designs, at once conceived for Semiramis the most violent passion. Her husband, upon hearing this, killed himself to escape the fury of Ninus. Having married her, he not long after died—some assert by her connivance—and left the kingdom to her.

It was Semiramis who undertook the building of the mighty Babylon, in which work she employed two million men. Dr. Prideaux tells us the walls around Babylon were three hundred and fifty feet high and eighty feet thick, and that it contained six hundred and seventy-six squares two miles and a quarter in circumference. His description of the walls, the quays and bridges, lakes, ditches, canals, palaces, hanging-gardens and temple of Belus presents a picture of grandeur and magnificence unknown in this age. Diodorus also says even in his time there were many monuments of grandeur still standing bearing the name of Semiramis.

This beautiful and extraordinary woman possessed the most marvelous control over all she came in contact with. Her simple presence was sufficient to quell any tumult or mutinous proceeding. Not satisfied with the immense possessions left her by Ninus, she conquered Ethiopia and the larger part of Africa. Not yet content, she determined upon the subjugation of India, against which

she set out with 3,000,000 foot, 500,000 horse and a multitude of camels, with which she thought to make head against the Indian elephants. After she had successfully crossed the river Indus the Indian King fell upon her army, with his elephants, with such fury that it was utterly routed. Semiramis was by this defeat compelled to give over the conquest of India. Having reigned forty-two years she resigned the throne to Ninyas, her son, whom she discovered was plotting against her life, as the Jupiter Ammon of Egypt had told her years before he would. She retired from the sight of men, hoping speedily to have divine honors granted her name, which was also prophesied for her by the Egyptian god.

Of these vast armies, which predicate still more vast population, Rollin remarks: “I must own I am somewhat puzzled with a difficulty which may be raised against the extraordinary things related of Ninus and Semiramis, as they do not seem to agree with the times so near the deluge; I mean such vast armies; such a numerous cavalry; so many chariots armed with scythes; such immense treasures of silver and gold, and the magnificence of the buildings. The temple of Belus alone contained more than twenty millions pounds sterling hoarded treasure.” Rollin argues that the Greek historians, from whom he compiled, must have fallen into some grave errors, since, that such things should have occurred so soon after the deluge, presupposes what must have been beyond the range of possibility.

The Assyrian empire, having attained the zenith of power and magnificence under Semiramis, began to sink into a gradual decay, the kings themselves setting the example of indolence and dissipation. This process of decay continued until the time of Sardanapalus, about 700 years B. C. He surpassed all his predecessors in effeminacy, cowardice and licentious luxury, and abandoned himself completely to pleasure, wine and women; even dressing and painting his cheeks as the women did. It seems strange that a people so used to glory and conquest should not have sooner revolted against such debauchery and dissoluteness. This was left for one Arbaces to do; he obtained entrance to the King’s palace, and with his own eyes witnessed the truth of the reports about the King. Arbaces at once began to incite rebellion; by his reports he gained over the governors of several provinces, who raised an army and marched against the King, whom they succeeded in shutting up in the city of Nineveh. The King considered Nineveh impregnable, but the river Tigris suddenly rose to a great height and broke down some portions of the walls of the city, which admitted the troops of the rebellious governors. Sardanapalus then proceeded to burn himself, his women and treasure, which latter, according to Atheneus, amounted to “a thousand myriads of talents of gold and ten times as much silver, each myriad of which was of the value of $7,000,000.” Such treasure we in this age know nothing of. After the death of Sardanapalus the empire was dismembered, and the kingdoms of Babylon, Nineveh and Medea formed from its ruins. Between these there was constant warfare waged. During the time of Cyazares a horde of Scythian barbarians devastated the three kingdoms, remaining their masters until the people disposed of them by a general stratagem—slaughtering them while drunk with wine, at feasts to which, by concert, each family of Assyrians had invited them upon an agreed day. Such as escaped this, fled the country. Cyazares, after repeated efforts, succeeded in utterly destroying Nineveh, the last city that held out against him, and with the aid of his nephew, Cyrus, united the three kingdoms again under one government, which was the beginning of the famous empire of the Medes and Persians.

Crœsus, King of Lydia, is here entitled to a slight digressive reference on account of the influence he at this time exercised. Vast riches in most kingdoms had led to indolence, effeminacy and licentiousness; but Crœsus thought it unworthy for any person, much less a king, to surrender himself to these. Not only was he vastly rich, and an extraordinary conqueror, but his chief delight consisted in literature and science; he patronized the learned and wise of all nations; so much so that they all made particular effort to visit his dominions to receive his assistance. His court was the ordinary residence of the seven wise men of Greece. It was with him that Æsop, the author of the Fables, flourished. The possession of these characteristics entitle Crœsus to most honorable mention and memory, and he should be regarded as a representative king.

It will be remembered that Cyrus was the first king of Persia, which by conquest he enlarged until it comprised all the territory between the Tigris and Indus, the Caspian Sea and Indian Ocean. His uncle, Cyazares, retained Medea. He, finding himself involved in a terrible war with the kings of several provinces—among whom was Crœsus of Lidya—sent to Cyrus for aid, who set out at once with an army. The vast preparations made on both sides culminated in the battle of Thimbra—one of the most remarkable events of ancient times—which decided the empire of Asia against the Assyrians and in favor of the Persians. This battle has always been the study of great commanders, because the military genius there displayed by Cyrus makes him rank as one of the greatest of generals. After reducing all the smaller nations of Asia Minor, Cyrus turned his whole power against Babylon, which he determined upon destroying. He accomplished its capture by emptying the river Euphrates into the vast ditches prepared by Semiramis, and marching his army over its dry bed into the city at night, while its inhabitants were engaged in some general entertainment. Thus the mighty city built by Semiramis fell, and the destruction ceased not, until not even its walls remained to tell

the story of its grandeur.

With the reunion of what constituted the first Assyrian empire, the conquests of Cyrus seem to have ceased. He turned his whole attention to perfecting a system of government for the vast country he had acquired. This he accomplished most wisely. All historians agree that in this task he was greatly aided by the wisdom and counsel of Daniel the Prophet, who obtained a position of great power and influence. It was no doubt he who obtained from Cyrus the famous decree regarding the Babylonish captivity of the Jews. So prosperous and happy did the empire become under the reign of Cyrus, that historians affirm “that after his death he was universally regarded as the common father of the people.” Having reigned seventy years he died 529 years B. C., leaving the empire to Cambyses, his son, who was as great in crime as his father had been in virtue. He caused the death of his only brother, Smerdis, married his youngest sister (who was very beautiful), and afterward killed her because she lamented the death of Smerdis. Happily his reign was cut short by death, having lasted less than eight years.

It was not generally known that Cambyses had caused the death of his brother Smerdis, which made it possible for Smerdis the magician to usurp the throne, giving out that he was the true Smerdis. He was exposed by one of his wives, at the instance of a nobleman named Darius, who managed to slay him, and was then unanimously named king, by his brother noblemen, for having done so. Soon after becoming king, Darius, with an army of 1,000,000 men, marched into Europe to chastise the Scythians for having overrun Assyria in the time of Cyazares. The expedition resulted disastrously to Darius, who could not even bring the Scythians to battle. They continually retired before him, and left him to be defeated by the scarcity of provisions, from which cause Darius came near losing his whole army, and was obliged to beat a hasty retreat to his own country. Darius then determined upon the conquest of India, which he accomplished. Of the particulars of this campaign no records are left, though it is known that India remained a Persian province many years, and paid annual tributes of £50,0000 sterling. Darius was the only conqueror who ever subjugated India sufficiently to reduce it to a tributary province; it made the twentieth that had been added to Persia.

During the reign of Darius, the Ionians revolted against Persian control, and succeeded in involving the Athenians with them; they furnished the Ionians twenty ships, by the aid of which Sardis was captured and burned. This so enraged Darius that he formed a solemn resolve to destroy Greece. Thus began that implacable strife of the Persians against the Grecians, by which Persian power was almost destroyed, and in which the Greeks performed the most remarkable exploits known in military history. These, coming more properly under Grecian summary, it will only be remarked here that Miltiades on the plains of Marathon, Leonidas at Thermopylæ, Themistocles at Salamis, Aristides at Plateæ, Leotychides at Mycale, and Simon at Eurymedon, taught the Persian monarchs that they were not to be subdued by them, though they should expend their mightiest power in their attempts.

So exhausted was the empire from the Grecian wars, that when the Egyptians revolted during the reign of Darius II. he found himself unable to subdue them. The superb empire made and left by Cyrus the Great under such admirable government was now becoming thoroughly corrupted and debauched, and was given to all species of licentiousness. Its former glory rapidly departed, and the elements of destruction were actively at work preparing it for the blow Alexander of Macedon was soon to deal it, from which it was destined never to recover.

After the dismemberment of the Macedonian Empire, Persia in part recovered, but became the field for constant barbarian inroads, which kept the kingdom in poverty and misery. Under Chosron, about the year 600, the empire again extended from the Indus to the Mediterranean. Justinian I. waged a successful war against Chosron, and compelled a disadvantageous peace. This was annulled by Chosron II., who again raised Persia to her former greatness by conquering Egypt, Ethiopia, Lydia and Yemen. These sudden conquests were soon lost, and the partially resuscitated empire passed into a rapid decline. At no time since has Persia exerted any considerable influence upon surrounding nations. Under Timour, in the fourteenth century, and the Turks in the fifteenth, it decayed rapidly; in the sixteenth century it became nearly extinct, and, as a nation, it remains virtually so to this day.

THE TENDENCIES OF GOVERNMENT.

[Revised from the New York Herald of May 9, 1870.]

VICTORIA C. WOODHULL’S FOURTH PAPER—A RETROSPECT OF ANCIENT GRECIAN AND ROMAN HISTORY.

[Below we present the fourth subdivision of Mrs. Woodhull’s treatise on “The Tendencies of Government,” from which it will be perceived that the lady has delved deep into the mines of governmental lore, and is vigorously training for the Presidential sweepstakes of 1872:]

Regarding the earliest traditions of Greece, it can be said they are less indefinite than those of Egypt or Assyria. No country of antiquity can be reverted to with more admiration and respect than this. In whatever light her history is considered, illustrious examples of true greatness abound. If her military career be reviewed, where can more glory be found to have been achieved? If her government be examined, where has greater wisdom and moderation ever been exercised? If the comparative advancement of science, literature, art and philosophy made within her domain be appealed to, where has greater proficiency ever been attained? If the personal characteristics of her great men be analyzed, where has patriotism ever risen to so sublime a degree? In many respects Greece may be considered the school-house of the world, wherein it has been taught the rudimentary principles of knowledge, especially that species of knowledge that conduces to the development of wisdom.

The territory of ancient Greece was by no means the Greece of to-day, but embraced all that country lying southward from Illyria and Thrace, now forming a part of Turkey in Europe. It then consisted of the provinces of Epirus, Peloponnesus, Greece proper, Thessaly and Macedonia, besides many islands in the Ægean Sea. The earliest inhabitants of Greece of whom anything is known were the Pelasgi, who "knew no other law than force, were ignorant even of agriculture, and fed on roots and herbs." A people called the Hellenes, from Asia, mingled with them, and their common name became Greeks, from Græcus, the son of Pelasgus. Although Greece was afterward the seat of so much knowledge and wisdom, it does not appear that these originated among the descendants of its original inhabitants, but that they sprung from the Phœnecian and Egyptian colonies that from various causes found their way into Greece.

Of the constant internal strife carried on between the several Grecian provinces no mention will be made. The first of these to arise was Sicyon, followed by Argos, Mycenæ, Athens, Sparta, Corinth and Macedon. When the population of any of these became large, it was the custom to send out colonies, thus distributing Grecian influence, instead of by war. The powerful cities of Rhegium, Syracuse, Sybaris, Crotona, Tarentum, Gela, Locris, Messina, Marseilles and Agrigentum, were formed from such colonies. For the space of a thousand years, or until 520 years B. C., the Grecians appear to have confined their operations within their own dominions. Being continually engaged in war with each other, they had no opportunity of carrying on aggressive warfare—this was never a Grecian characteristic, though so forcibly illustrated by Alexander of Macedon, and by Cimon and Agesilaus, for retaliation rather than aggression.

It is to be specially observed as illustrating the part Greece performed in the general advancement and diffusion of civilization that while all other great nations were made so by aggressive conquests, Greece rarely ever made war except in self-defence. The influence other nations had upon the world was gained by conquering contiguous countries. The influence Greece exercised was by diffusing among other nations the principles of science, philosophy and government and by commercial intercourse. Thus it is found that up to the time of the first Persian invasion there had been no concentration of the military forces of the several provinces, except as they had taken sides against each other in their feudal wars.

The Persian attempt to subjugate Greece was most unpropitious from the very onset. Mardonius marched a large army into the very heart of Greece, with scarcely any opposition; but his fleet, in approaching the coast of Macedon, encountered a storm, and was destroyed. Meanwhile, Mardonius took no pains to encamp his vast army in a place or form of security. A mere band of Thracians, taking advantage of this, fell upon the Persians in the night, and completely routed the whole army. This double defeat, by such unexpected means, caused Mardonius to return quickly into Asia.

Nothing daunted by this defeat, which he attributed to the inexperience of Mardonius, Darius dispatched another army, consisting of 500,000 men and 600 ships. The fleet first captured Eretrea, while the army caused such consternation in Greece that only Sparta, of all the provinces, responded to the Athenian call for succor. The Spartan troops, even, did not arrive in time to participate in the battle of Marathon, where Miltiades, with 10,000 Athenians, completely routed the whole Persian army. This victory gained by the Greeks over an army outnumbering theirs nearly twenty times, was, no doubt, the inspiring cause by which all succeeding victories over the Persians were gained. It taught the Greeks that a few determined men, fighting in defence of their country, were mightier than a multitude with no such incentive. Through the course of succeeding ages the Grecians exhibited a noble emulation of, and desire to imitate, if not excel, their ancestors, who fought and conquered at Marathon.

Xerxes, the successor of Darius, persisting in his determination to destroy Greece, crossed the Hellespont on a "bridge of boats," with an army of 1,700,000 and 80,000 horse, to which submitting countries added 300,000, so that he appeared before the pass of Thermopylæ with 2,000,000 men. Against this force Leonidas opposed 12,000 Spartans and allies. The whole power of the Athenians had been turned into preparations for naval warfare, which, as the sequel showed, was the salvation of Greece. The manner in which Leonidas and his 300 Spartans defended Thermopylæ, still further raised the determination of the Greeks to resist

after the same fashion all movements of the invaders. On the same day as the battle of Thermopylæ a great, though indecisive, naval battle was fought at Artemesium. Xerxes advanced upon, captured and burned Athens. The fate of Greece seemed decided; but the great naval battle of Salamis entirely changed the face of affairs. Xerxes being secretly informed that it was the intention of Themistocles to proceed with the Athenian fleet and destroy his “bridge” across the Hellespont, precipitately abandoned Greece, leaving Mardonius with 300,000 men and instructions to subdue Greece “if he was able.” At the battle of Platæa, which soon followed, Mardonius was completely defeated, and the same day the remainder of the Persian fleet was destroyed at Mycale.

Having thus rid themselves of the Persians the Athenians set about to rebuild their city. The Spartans, fearing Athens would gain great naval superiority over them, opposed it; thus the Grecians were no sooner rid of a common foe than strife broke out among themselves. This tendency arose from the process of individualization and is specially illustrative of the progress of evolution. Athens was rebuilt, and, as the Spartans feared, soon exceeded all other States in power and splendor. Athens also became the centre of the arts and sciences, knowledge of which was at this time rapidly developed. Sparta, no longer able to endure the overbearing pride of Athens, brought on the Peloponnesian war. This war devastated Greece and enslaved Athens. Sparta in turn was compelled to yield to Epaminondas, the Theban. In spite of this terrible war, poets, philosophers, artists and statesmen continued to arise, commerce flourished and the customs of the people were raised to the highest degree of perfection.

But a time of unhappiness soon came upon this too prosperous condition. Philip of Macedon, bold and cunning, took advantage of the dissensions that at all times prevailed, and by a sudden _coup de main_ thought to make himself master of all Greece. It can be asserted that not Greece, but one man, for forty-eight years continually frustrated the designs of Philip, who himself said, “The eloquence of Demosthenes did me more harm than all the armies and fleets of the Athenians. His harangues are like machines of war and batteries raised at a distance, by which all my projects and enterprises are ruined. Had I been present and heard that vehement orator declaim I should have been the first to conclude that it was necessary to declare war against me. Nor can I reach him with gold, for in this respect, by which I have gained so many cities, I find him invincible.” Antipater also says of him, “I value not the galleys nor armies of the Athenians. Demosthenes alone I fear. Without him the Athenians are no better than the meanest Greeks. It is he that arouses them from their lethargy and puts arms into their hands almost against their will. Incessantly representing the battle of Marathon and Salamis, he transforms them into new men. Nothing escapes his penetrating eye, nor his consummate prudence. He foresees all our designs; he countermines all our projects and disconcerts us in everything. Did the Athenians confide in him and follow his advice we should be irremediably undone.”

From all that can be gathered about this remarkable man it may seriously be considered whether, had he had the power of a Sesostris, a Cyrus or an Alexander, he would not have conquered and ruled the world. But the Athenians failed to follow his advice, and were reduced to submission to Macedon by the youthful Alexander, who said of him, when he passed Thermopylæ, “Demosthenes called me a child when I was in Illyria; he called me a young man when I was in Thessaly: I must now show him before Athens that I am a man grown.”

After the conquest was complete Alexander summoned at Corinth representatives from the several Grecian States, and requested from them the supreme command of all their armies against the Persians. No assembly ever held was embryotic of more momentous events. It was the Western World taking counsel and resolving upon the destruction of the Eastern, and was the initiatory step to almost incredible events, and to the revolutions that were to change the condition of the whole world, through the unexampled career of him who caused its assembling.

After the death of Alexander, the several Grecian States renewed the struggle for freedom. The Romans, who had risen in the West, becoming involved in the strife, proved fatal to Greece; for in the year 146 B. C. the capture of Corinth reduced Greece to a Roman province.

During the whole period of strife from the battle of Platæa, the arts and sciences flourished in a most extraordinary manner. Indeed, it was the golden age of art. The Grecian colonies were still more prosperous than their mother country. Alexandria, in Egypt, especially, became famous as the seat of learning. In the time of Augustus, the Greeks lost even the shadow of their former freedom and ceased to be an independent people; but they became the instructors of their conquerors; for their language, manners, customs, learning, arts and tastes spread over the whole Roman empire. After a time the Romans came to esteem the Greeks as the most worthless of creatures.

Asiatic luxury, acquired from the Persians, had wholly corrupted the Greek’s ancient love of freedom, and a mean servility became substituted therefor. At the beginning of the fourth century the people scarcely showed a single trace of their former noble

characteristics of simplicity and grandeur; and thus Greece passed into her condition of unimportance.

ROME.

Rome originally was but an insignificant city, founded on the banks of the Tiber by some herdsmen, whose small numbers were swelled somewhat “by strangers and outcasts from all the country about.” The herdsmen were without doubt Pelesgians, who had previously occupied the more easterly portions of Europe. The language they introduced bears unmistakable evidence of similarity to the Greek. That a people so humble as the original Romans were, who labored principally upon an unproductive soil for sustenance, should have increased in numbers, power and influence, so as to rule the world, seems almost incredible; but so it was.

A three-fold division of the people was early spoken of, probably representing as many different tribes. Each of these tribes was divided into ten smaller bodies called “Curial;” in war these divisions were represented by thirty centuries that made up the “legion.”

There were very few women among the early Romans. They seized on some Sabine women who came among them to witness their games, which seizure caused a war with the Sabines; the result of the war was the union of the Sabines with the Romans, and the extension among them of the same rules and divisions that existed among the Romans. This first conquest was prophetic of all future conquests, terminating as it did by the conquered country being added to Rome to increase its territory and power. The system of conquest thus begun continued with more or less activity during four centuries, when Rome had acquired nearly all the country as far east as the Euphrates. 500 years B. C. Tarquin, the last king, was expelled by the Senate, and the Roman republic began. During its first century, contentions among themselves prevented the Romans from materially extending their conquests. About the eightieth year of the republic the Gauls first attacked, captured and plundered Rome; nor could the Romans expel them until the banished Consul Camillus was recalled to command the armies. Soon after this, rapid strides to greatness were made, and Rome became the centre of attraction for the world. All countries, not already Roman, sought alliance, thereby hoping to escape conquest.

It was during this time of glory that luxury was first admitted and practised by Romans; and, as in all other countries, it laid the foundation for future ruin, by introducing into use licentious, vicious, and effeminate practices, where simplicity, purity and honor had previously held full sway.

Two hundred and eighty years B. C. the Carthagenians forming an alliance with the King of Syracuse brought on the first Punic war. The Syracusans soon deserted to the Romans and ever remained constant to them. The Romans had now acquired such love of, and thirst for, glory that they were considered unconquerable. In Sicily they gained great naval victories, and Africa trembled when her fleets neared its shores. The Carthagenians, through the advice of the Lacedemonian, Xantippus, defeated the army commanded by Regulus and captured him; he subsequently lost his life at the hands of the Carthagenians for opposing at Rome the conclusion of peace. The war continued by the advice of Regulus, turned in favor of the Romans, and the Carthagenians were compelled to accept the terms of peace offered by the Romans, thus ending the first Punic war.

The conquest of Seguntum by the Carthagenians, contrary to the terms of peace, led to the second Punic war, in which the celebrated Hannibal figured so conspicuously, and for a time made Rome tremble. From this temporary fear the Romans emerged more terrible than ever. They not only put a stop to the victorious career of Hannibal, but conquered Spain, and, crossing into Africa, compelled the recalling of Hannibal to defend Carthage. The famous battle of Zama ensued, in which both Hannibal and Scipio displayed the greatest military talent. The study of this battle has since been the admiration of all great military captains. The victorious Romans dictated again the terms of peace, which Carthage was obliged to accept. Thus ended the second Punic war.

The ambition of Rome now increased to such an immoderate extent as to threaten the reduction of the whole world to submission. Macedon and Syria endeavored to make head against them, but nothing could withstand the irresistible power of the perfectly disciplined Roman legions. Macedon was glad to end the war by becoming a Roman province, and Syria, to escape total destruction, by ceding to Rome the larger portion of her territory.

Carthage, the former powerful rival of Rome, still existed, which so annoyed the Romans that its destruction was determined upon and accomplished by the third Punic war, which ended 145 years B. C. The complete subjugation of all the Greek and Spanish provinces immediately followed, and Roman power was unparalleled. This begat a spirit of intolerance which goaded many of her conquered provinces into revolt. Combining their armies, they for a time successfully resisted the Romans. Pompey, coming into command, rapidly crushed out all resistance. Internal contentions between the several factions at Rome quickly followed the

reduction of the formidable revolt. Cæsar, Pompey and Crassus, more active than the rest, divided the government between themselves. This was the first triumvirate. Cæsar would have no equal, and Pompey could endure no superior. The rivalry between these two powerful men was the initiatory step to the conditions that ruined the republic. Cæsar obtained the consulate and government of Gaul, and began to lay the foundation for his future greatness by extending his military enterprises in all directions. He defeated the Swiss, conquered the Germans, subdued the Belgians, reduced the whole of Gaul, invaded Britain, imposed tributes upon the people everywhere, and became the master spirit of the time.

When Cæsar returned to Rome Pompey fled. Cæsar then became perpetual dictator. This was about 50 years B. C. Pursuing Pompey into Greece, Cæsar defeated him at the great battle of Pharsalia, and thus overcame all opposition to unlimited power. In this possession Cæsar became so intolerably overbearing that a conspiracy was formed against him, which resulted in his death at the hands of Brutus. The love of the people, especially the women, remained Cæsar's, so the new ruler found no peace. The strife between Brutus, Antony, and Octavius waxed warm, and Rome, as in the days of Marius and Scylla, became the scene of infamy and horror. Octavius and Antony, overcoming all opposition, divided the empire between them. Octavius remained in the west, Antony went to the east, and there became enamored of Cleopatra, the Egyptian Queen, for whom he abandoned Octavio, the sister of Octavius. This brought about a conflict, and Octavius proceeded to the east with a great army to chastise Antony. By the treachery of Cleopatra, whose army and navy deserted to Octavius, Antony was totally defeated. The treachery of Cleopatra determined him to take his life, which in turn caused her such grief that she sought and found relief through the aspen's bite.

Octavius thus became sole master of the mightiest empire the world had ever beheld. It comprised nearly every country then known under a universal monarchy. Octavius assumed the title of Augustus Cæsar, and reigned over this mighty empire forty-five years with the most consummate skill and prudence, and with a profound appreciation of the position he occupied. It was during his reign that literature flourished so extensively. The best literary age of all countries has since been called its Augustan age, as likened to that of Rome under him. In the thirtieth year of his reign Jesus Christ was born. The Roman Empire at this time assumed its proudest and grandest pitch of power and glory, which will ever be the wonder and admiration of coming ages, until another nation shall arise to a greater and still more glorious condition, of which Rome will forever remain prophetic until fulfilled.

From the reign of Augustus to Constantine the Great, who transferred the capital to Byzantium, the empire sustained a series of good and bad rule, and declined somewhat from its previous proud position. On the death of Constantine the Great, Constantine II., Constantius and Constance divided the empire. Constantine II. had all Europe west of the Alps; Constantius Italy, Sicily and Africa; and Constance Asia, Egypt and the whole East. This division was the beginning of the great disasters that came fast upon Rome. Constantine and Constantius being disposed of by treason, Constance usurped the whole power; being destitute not only of all capacity for so extended rule, but also of all honor, the empire began to disorganize. During his reign and that of his successor, until Theodosius, about the year 400, country after country successfully revolted against the power of Rome. Everything in which her former renown and glory consisted degenerated, until Rome was precipitated into that condition which ultimated in her entire destruction, so that she who so lately was the proud mistress of the world, was unable to resist the barbarians of Northern Europe, who extinguished her light, thereby leaving the world in the midnight and anarchy of the "Dark Ages."

MODERN EUROPE.

With the downfall of Rome that portion of history called ancient ceases. The numerous provinces of Europe that had been under the Roman power were completely under the control of the various barbarians who had destroyed that power. Out of this condition of anarchy modern Europe rose. As it consists of a number of countries their separate histories will not be considered; only such prominent facts regarding the whole will be observed as seem to indicate and mark its general progressive steps.

From the fall of Rome in 476 to the time of Charlemagne in 800, Western Europe was the scene of those operations that determined its present divisions. The barbaric tribes that occupied it were the Vandals, Suevi, Alans, Visigoths, Burgundians, Germans, Franks, Lombards, Angles, Saxons and Huns. The Visigoths founded Spain; the Angles and Saxons formed the seven kingdoms of Britain; the Germans fixed themselves on the Danube, and from these grew all the German States; the Lombards had Italy, and the Franks France. During this period Mohammed founded an empire in Asia, out of the ruins of which most of the monarchies of Western Asia arose.

Charlemagne was the ruling spirit of what may be termed the second period of modern European history, from 800 to 1074. Under him France took form and rank as one of the first powers of the world, and has never since been entirely divested of it. He temporarily re-established the Western Empire, but with his death it went to pieces. Spain was the theatre of the terrible wars

between the Moors and Christians. The seven Saxon kingdoms were united by Egbert, who became the first King of England. The whole north of Europe was still barbarous, and frequently poured its hordes over the civilization in the south that was struggling for existence. The Danes ravaged England, and became masters of it; while Germany, under Otho the Great, rose to great power. The other present European States were still in obscurity.

The third period of modern European history extended from 1074 to 1453. During this period the German Empire was the scene of constant quarrels between the Emperors and the Popes, under the factions called Guelphs and Ghibelines, which dimmed the lustre Otho had conferred on it; Naples and Sicily were erected into kingdoms by the Normans; Denmark arose to some importance under Wildemar II.; in France, legislation and police restraints were introduced, but her power was nearly crushed by Edward III. of England, which country was in turn deluged in blood by the “Wars of the Roses;” Genoa and Venice increased in rank and importance; Spain still suffered from the Moors; Portugal became a distinct kingdom; Sweden and Norway came into existence; Russia emerged from the barbaric rule of the Tartars; Poland put on the royal dignity; Hungary and Bohemia were added to Austria, and the Turkish Empire rose to great power, putting an end to the Eastern Empire. The arts and sciences began to be cultivated again in the West, and literature and learning to flourish. Many inventions were produced, such as paper making, printing, engraving, painting in oil, gunpowder, and the mariner’s compass, and this brings us to the fourth period of history, which was pregnant with events that were to modify and change the general conditions of the world.

The fourth period extended two hundred years to 1650. In it America and the West Indies were discovered. The Reformation brought about great changes in very many respects in nearly every European country, many of which underwent important revolutions. Germany made important legislative improvements; feudal government was destroyed in France; Spain became a Christian kingdom; England rose to great power, especially under Elizabeth; Italy divided herself into numerous small States; Switzerland became a republic; the provinces of Holland declared their independence of Spain; Poland flourished; Denmark became of importance; affairs in Russia assumed a new appearance, the power of the Tartars being destroyed, and the Ottoman Empire became grand under Solyman II.

About 1650, the beginning of the fifth historic period, the political systems of Europe began to undergo considerable change, which, from various causes, continued until the time of Bonaparte. Revolutions in England, France, Germany and Russia caused various modifications, not only in the limits of the various countries, but also in their governments. England and France seemed to divide the other Powers about equally in the support and continuance of their wars; the general configuration of Europe, however, did not sustain any radical changes. This period is important in another and new aspect. Colonies from all the western kingdoms were continually going to the new America—that country which should in future exercise such control over the destinies of the world.

From time to time in the history of the world there have arisen single great men who by the grandeur of their enterprises and the power of their intellect and ambition, have left indelible impressions of themselves upon its history and condition. Such were Sesostris, Cyrus, Alexander, Cæsar and Charlemagne. Though they all possessed many traits of character which the present age cannot admire, they must ever be regarded as having given general civilization those great impulses that have so rapidly evolved the world from barbarism.

At the beginning of the next period another great man appeared, the waves of whose power were felt over the whole world, and who, by the grandeur of his conceptions, power and executive will, rose from obscurity to dictate to Europe, which was at that time the world. From 1789 to 1815 may justly be styled the Bonapartean period. It would be superfluous to recapitulate his career; nor would it be less so to trace the rescuing of America from the savages by the resistless advance of civilization, which, since the settlement of Jamestown, in 1607, has made such unexampled progress in all things that pertain to greatness, grandeur and glory—in literature, science, art and government.

Before closing the _resume_ of general history it should be observed that many great events have been passed unnoticed, the principal aim having been to follow the western tendency of empire, and to present only such facts as were prominent in forming standards of progress, perpetual landmarks and historic eras. In Asia particularly, great events occurred, such as the career of Ghengis Khan and Tamerlane. The former, it is computed, slaughtered fifteen millions of human beings during his reign. The efforts of such as he were the last struggles of barbarians to arrest the onward course of general progress. Though for a time triumphant in their course the genius of progress could never be entirely eradicated where once it had found root and growth. China and India have been passed because, for the most part, they have been confined within themselves; the reason whereof will be discussed hereafter.

THE TENDENCIES OF GOVERNMENT.

[Revised from the New York Herald of May 16, 1870.]

VICTORIA C. WOODHULL'S LAST LESSON IN POLITICAL HISTORY.

[The following communication from Mrs. Woodhull, who, as the public is already informed, has devoted herself to enlightenment on the question of government, will be found as interesting as any of her previous letters on the same subject This is Mrs. Woodhull's concluding letter on the Tendencies of Government:]

In entering upon the next and third part of the subject, we are conscious of the imperfect construction of the second. It must be remembered that the purpose of the _resume_ was not to give consecutive historic detail, but to mark such special facts as evidently show there was a progressive and consecutive rise and fall of nations. Without apology for omissions and minor errors, we proceed to the consideration whether the facts elicited from history form a consecutive chain of progress, by which the world has been evolved from barbarism, and whether this evolution has been according to present philosophic formulas. The first and most prominent fact that becomes obvious to the observer of general history is that the progress of empire has always been from the east, westward. The progress of the earth in its daily rotation upon its own axis and also in its orbital movement around the sun is toward the east. This is believed to explain the order maintained by the course of empire. Motion being in the direction of the least resistance, the general tendency of the surface influence of the earth must be west. Counter side influences have at times caused deviations from straight lines, but this only makes the general proposition still more forcible. Therefore, as a general proposition, the course of empire and of civilization and population has always been westward.

If this proposition is applied to pre-historic times, to govern deductions regarding it, neither Assyria nor Egypt can be considered as having been the first powerful empire of the world. It is known that in them there existed a numerous and powerful people of whom history fails to give the exact or even supposed origin; the same is true of all the surrounding countries, in Europe, Asia and Africa. If it is allowed that population has resulted from the same general law that civilization has, it must be admitted that China and India were the predecessors of Assyria and Egypt.

Allowing that China and India existed as vast tribal communities previous to the historic age of Assyria and Egypt, it will be seen that population, general civilization and improving government crossed Asia westward and developed the Assyrian Empire, which, for the same general reasons must be held the predecessor of Egypt.

The Assyrian Empire attained its greatest power under Semiramis, 2,150 years B. C., which was about the beginning of the historic age of Egypt, and 700 years before Sesostris conquered the greater part of the known world. In whatever comparative light the histories of these two countries are viewed, Assyria must be deemed the more ancient empire. It may be further observed, if Nimrod was the first King of Assyria, and the father of Ninus, who was the husband of Semiramis, the empire came to its greatest glory in an exceedingly short time. Very many reasons can be assigned why Assyria must have been an empire of centuries when Semiramis reigned.

The Assyrian Empire, in the year 2,150 B. C., was the great power of the world, having sway over the greater part of Asia and Africa. Seven hundred years afterward, or 1,499 years B. C., Egypt had risen to its greatest glory, and under Sesostris acquired the Assyrian Empire, besides a vast country in Europe and Africa which Semiramis had never subdued.

Out of the ruins of Assyria, Babylon, Nineveh and Medea were formed, and, after being consolidated, were merged into the famous Persian Empire by Cyrus, 536 years B. C., or 950 years after the proudest Egyptian period. The Persian Empire absorbed the Indian and Egyptian, and became the most splendid power that had existed, and with rising Greece divided the world.

Grecian power being concentrated by Alexander of Macedon, he acquired the ascendancy over the Persians, and became the world's conqueror. Numerous Grecian colonies, following the general tide of influence westward, formed powerful kingdoms in various parts of the Mediterranean coasts and islands.

Rome, rising to power, contended with Carthage for supremacy in the west. Carthage being destroyed by the three Punic wars, the attention of Roman armies was turned eastward, to gather in the elder empires that were verging on decay. Greece, 146 years B. C., became the Roman province of Achaia. Continuing its conquests further, fifty years B. C., Rome became ruler of a greater part of the inhabited world than any of the previous empires, and existed in the utmost pomp and glory several centuries, until the northern barbarians swept over and extinguished it.

No considerable Power existed after 476, until Charlemagne's, though some influence attached to several Asiatic countries. Civilized nations were extinct in Europe. From Charlemagne, in 800, to 1500, civilization continued to rear its blighted head in various parts of Europe, and to mark the countries that should play the next last act in the drama of unceasing general progress.

The historic age of the world, then, has been occupied thus: The Assyrian Empire existed and was subdued by the Egyptian, which was conquered by the Persian, which was destroyed by the Grecian, which was compelled to yield to the Roman, which was destroyed by the barbarians, that from its ashes numerous kingdoms and empires should arise, to exist together, and to spread over and occupy the outside world Rome had never known.

From this succession of empire many deductions might be drawn which would assist in forming a well-defined line of progress. Many are so obvious that it would be superfluous to name them; therefore we leave them, with the general observation, that in each succeeding empire the condition of the people was more directly and distinctly recognized, while each, in grasping for universal sway, and not possessing the principles upon which universal government was possible, exceeded the limits of its central strength, and thereby fell. India and China alone, of all ancient nations, survive, because they have never sought to extend their limits, but have expended their strength within their own, though it often was in war.

The commercial greatness of England, more than any other present externally apparent power, is promoting the general assimilation of the world. This influence is producing very great and diffusive results in Asia, Africa and South America, and the way is being opened and cleared for more radical and general control. It is impossible that the increasing power of civilized and enlightened ideas and customs in India, China and Asia generally, should not revolutionize those countries. Many Chinese will return from this country, carrying with them the solvent power of the genius of our institutions, which, combining with all similar powers, will ere long kindle the flame of popular individual freedom. This flame will cause republics to spring into existence where one form of government has existed through historic time over the same defined limits of kingdom. Another great and powerful influence is being evolved that cannot fail to exercise a tremendous modifying power over Asia. Russia, the European giant, is slowly but surely pushing into Asia from the west. If it continue its present well-consolidated home strength, it will absorb Asia until it meet the same absorbing process proceeding westward, when Asia will be prepared for a still grander consummation.

In Europe, Russian influence is also gaining the ascendancy. Though one of the youngest of European kingdoms, it seems possessed of an inherent strength superior to them all, which Bonaparte, with all his terrible power and ambition, could not scatter nor weaken, and which stands ever ready to gather under its protecting wings the sickening adjacent kingdoms. At present Russia is biding her time and strengthening her arms, which she is conscious shall soon reach out and grasp all they can compass.

Prussia, meantime, is spending its strength in the vain, though apparently successful, endeavor to consolidate a country under absolute control, that is impossible of a people so numerously and diffusively represented, in a country where freedom is the rule. Throughout Southern, Central and Southwestern Europe, republicanism impatiently awaits the time to burst forth, and sweep among the debris of the past all traces of monarchy. The country over which the Roman eagles triumphed will again be under a republican form of government, improved upon that of Rome by 2,000 years of successful experiment. Russia will then occupy a central position between the republics of Europe and Asia, and its emperors be the last to yield their crowns. Like no other country, Russia has vast possessions in the unyielding frigid zone, which gives way but slowly before the gradually equalizing temperature of the globe, and of the character of which Russian Government naturally partakes.

Though revolutionized, Southeastern Asia will remain China and India, the ancient Assyrian, Persian and Grecian Empires will be resurrected under the consolidated Russian, while Africa will be left for Egyptian control, the promise of which begins to be visible in the direction given to civilization and commerce by the successful accomplishment of Nechos' defeated project, and, Egypt returned to be a nation of importance. Africa will naturally gravitate to Egypt, as it is possessed of no other salient point from which dominion and power can spring. In this regard Africa differs from all the other grand divisions of the globe. The character of its inherent wealth is also different. Other countries have their frozen regions, inland seas and marshes, stupendous mountains and deep jungles, but Africa alone has its Sahara. Commerce has scattered the germs of civilization here and there upon the coasts of Africa, but its central portions are to all intents as undeveloped as when Semiramis went into Ethiopia, and Sesostris levied his tributes of gold, silver, precious stones and woods. What Africa is held in reserve for by the general economy of the universe it is impossible to determine; but that a time will come when her resources will be required and obtained, is philosophically certain.

In Europe, where the more prominent scenes of modern history have been enacted, a modified method of conquest was begun by its countries, resembling that which was pursued by ancient Greece. This was not so much a subdual of foreign countries to actual

control as it was the general diffusion among them of civilization upon a more extended scale, made possible by improvements in the art of navigation. The assimilation of the world was thus begun upon a more perfect basis than by force of arms, and which differed widely from it in this fact: that while arbitrary control was at all times open to overthrow, the process of becoming alike, could never be interrupted except by the suspension of intercourse. Under the former, no two empires could exist side by side for any length of time without one being subjugated by the other; under the latter a number of kingdoms have existed for centuries, and though frequently engaged in conflict to settle some dispute of boundary or policy, it has seldom been pursued to utter destruction. The same end grasped for by Semiramis first and by Bonaparte last is being reached by the much more certain though gradual process of assimilation.

Thus far America has been untouched, but its consideration now becomes necessary. The Old World, as has been found, must continue its evolution, until like conditions shall exist everywhere. Similar interests beget union. When the general people shall begin to realize that their common interests depend upon the interests of each individual, one system of government must follow, whether it proceed from one common centre or from several centres.

What is America? Americus Vespucius and Christopher Columbus, acting upon sound scientific principles, discovered to the inhabitants of the Old World a new country, that was to be a haven of retreat for such of them as sought greater freedom and better equality, in which individuality could expand without coming in contact and being dwarfed by personal government. In continuing to be this haven of retreat it has become the representative country of the world. To its hospitable and ever-inviting shores people of all nations and climes have come, so that in two centuries the principal country of it has grown to be a Nation of more inherent strength than any country of the Old World, and to rank among its nations as a first class Power, both feared and respected.

The United States of America, all genuine Americans believe, will become the United American States. The very name is prophetic of what shall be, while the progress made in that direction begins to give well-defined outlines of it. Beginning on the Atlantic coast an infant republic, the United States has stretched its arms westward across the Continent. The same oceans that bound the east and west of the Old World wash its eastern and western shores. Having gained ocean-bound limits latitudinally, which form a central basis of strength, it will expand longitudinally until it shall become an ocean-bound republic—a grand confederation of States and interests, which, while being peculiarly American, will be so far cosmopolitan as to represent the descendants of every nation of the world—we no longer say of the known world. Europe has its well-defined limits of kingdoms and states, the people of which seldom pass from one to the other to become citizens; so also has Asia, while Africa is more nearly homogeneous; but they all give up their people to America. America, besides being American, is European, Asiatic and African, while each of these is becoming American. No well-informed person doubts that the progressive greatness, of republican forms of government, is rapidly dissolving the strength and solidity of all the monarchies of the Old World; though they may affect to despise republics, and to call ours a failure, their subjects are anxiously asking, When can we successfully revolutionize? Though such a step may not be openly advocated by any, it is, nevertheless, secretly discussed, and preparatory means are being devised, in every country.

And for these reasons the United American States will be the representative country of the world. Some may argue, because the commercial power of England is so superior; because she has such numerous general possessions, the English language being the one that must become universally used, that, by virtue of these, that dignity belongs to England. The fact cited above, showing that the general disintegrating influence of the world centres and is integrated in the United States, is a sufficient answer to such an illegitimate argument—illegitimate, because it is evident to all, that the process of the diffusion of English influence throughout the world is, so far as England is concerned, one of disintegration; while that going on upon American soil is diametrically opposite, being most decidedly one of integration. If the process of integration is pursued until it culminates, and the argument is educed that disintegration must follow in America as it has in England, it may be answered that the English influence that is being diffused world-wide is peculiarly English; while, when that process shall have commenced in America, it will proceed from a centre formed by previous influx from all countries in the world, and in this sense is not a process of disintegration, but simply of reaction.

The general law of direction for population and civilization was westward until it had encircled the globe, and in their last conquest found a country of sufficient inherent vitality to attract all other countries toward it. Not only does the tide of influence continue to flow to America from the east, but since her power has made itself felt upon the Pacific coast, the same tide has set in from the west, and Asia pours her surplus population upon our western coast, which exemplifies one of the modifying portions of the rule of motion. For the time, therefore, though preponderant commercial importance must be accorded England, the United States thereby loses none of its general prestige as the representative country of the world.

From whatever point consideration begins, the conclusion that is inevitably reached is, that the world must, in due time, become subject to one system of government. Whether that system shall at first proceed from one common centre or from several centres, is not so presently apparent, though that such a consolidation will be ultimately reached no one can doubt, who gives proper weight to the established fact that all perfect things become universal. So it is with everything of vital interest to the general people; rapid and sufficient communication is the only limiting power that controls their diffusion. In proportion as the diffusive means increase, in number and extent, so do the interests of the people become proportionately assimilated and best systems prevail.

A striking exemplification of the benefit that would flow from the adoption of general systems in all things may be drawn from the system of international telegraphing. A universal language in this becomes of the first importance. How much more important when the general uses and benefits are considered. The adoption of a universal language would remove the greatest obstacle from the path of the general diffusion of knowledge and innumerable difficulties from methods of communication.

It should be further observed, that the same law governs in all communications between the different countries. This is a necessity, in order that the intercourse may be preserved and be at all times safe. Should it be inquired, how much of the common law of the world is similar, the answer returned would astonish all who had not given it consideration, by being so considerable a portion of the whole. Were the inquiry pressed further, to find how great modifications of common law would be required in the various nations to make a common administration possible to all, a still greater astonishment would be developed by the slight disparities that would be shown to exist.

It has been remarked that England has possessions in very many latitudes and longitudes of the world. Over these possessions a governing control is exercised, which control foreshadows the possibility of a government that shall control every country in all latitudes and longitudes. When it is remembered that the countries of Asia are practically as near Washington as California, there can be no argument deduced from distance against a common and world-wide administration of government. The broad assertion is made, that there is no argument against universal governmental administration, but that every possible argument urges all people to prepare for it as the thing of all things to be desired by them.

It only remains for some one of the great countries of the world to arrive at, or to approximate to, a perfect system of government that shall contain the elements and principles of sufficient inherent strength, to insure to that country the power which shall control the destinies of the world. From what has been said regarding the position of the United States, it must be admitted, that nearly all the natural advantages, as well as the general order of things, are on this side of the globe. If any conclusions naturally flow from the observation of the past tendencies in the order of nature, they are that the United States is destined to be the centre of a universal government.

The tendencies of government from earliest historic time have persistently been to universal sway. The systems and forms through which this tendency has been manifested have changed from time to time, as the circumstances that created them—the environment—the sum total of the governed—have changed. These systems will continue to be modified, until this tendency shall have opened such channels for itself, as will permit free and untrammeled action; until these channels shall have encircled the world, and its utmost limits shall have been attracted within the realm of its positive flow and negative reaction, and until the commanding magnetic influence that shall proceed from its central seat of power shall reach all subjects and find in their general heart an answering response of fidelity and confidence.

In such fidelity and confidence each and all can safely and earnestly devote themselves to the best aims and wisest purposes of life—to intellectual, moral and spiritual growth. In this general and universal pursuit the millennium, so long prophesied and prayed for, can alone be gained, through which reaching, the government of heaven can alone be administered on earth.

Government, then, will be no longer one of physical force, but of the more powerful control of wisdom, including, perhaps, modified forms of force. Caste will no longer be distinction regarding material position or possession, but in moral and spiritual position and intellectual possession. In such government and caste a true aristocracy can exist in the midst of a true democracy. All will be born free and entitled to the inalienable rights of life, liberty and the pursuit of happiness in self-chosen paths, which alone is perfect equality. Perfect equality in the order of nature does not presuppose that all shall be alike, but it does presuppose that all shall be equal in the right to apply their natural or acquired talent according to the dictates of the power that governs them—the same as the flower and the tree follow their natural courses, and are equal, but not alike. As the lightning and the sunshine, the mountain and the river, the bird and the bee, the earthquake and the storm, follow their natural courses and tendencies under the government of the universal God, so shall the people follow theirs under a universal social government, when fashioned after the same general

principles that obtain in the domain of nature. For

Honest nature's voice shall give The laws to man by which he'll live.

It will be seen, then, that the philosophic formulæ that it has been demonstrated the evolution of matter conforms to, apply with equal force, effect and directness to the evolution of society, which is the fruit, so to speak, of the evolution of matter. The evolution of society, then, is "a continuous establishment of psychical relations within the community, in conformity to physical and psychical relations arising within the environment, during which both the community and the environment pass from a state of incoherent homogeneity to a state of coherent heterogeneity, and during which the constitutional units of the community become ever more distinctly individualized." Thus it has been from the earliest existence of communities, and this formulæ applies to all communities, whether Assyrian or American.

The process of revolution in its ultimate effects brings about a perfect state of action and reaction in all the various productions of nature, by which they are first perfected and then destroyed. The process in society must also continue until an equilibrium shall have been attained between the governing power and the power governed. When this is reached its perpetual continuance will depend solely upon the perpetuity of that over which it acts, or upon continuous individual existence. Continuous existence does not belong to the kingdoms below man, but does to man, from the fact that inherent within his consciousness there is a persistent though utterly unexplainable and undefinable knowledge of continuous existence, which is forever independent of all the changeable circumstances of the purely material, and which represents in him that characteristic of Divine power exhibited everywhere in the universe which is forever beyond scrutiny and limitation.

This evidence of Divine power within the individual, then, is the distinction between man as the product of nature and all other products of nature; while the consciousness of its existence is the direct evidence to the understanding that as the Divine power is eternal, so must that within be, which partakes of it, or is made up of its essential attributes.

It becomes the duty, then, of each individual who can catch but faint glimpses of such a consummation as universal government, to point it out and to assist by all legitimate means in the dissemination of light upon it and all relevant subjects. It becomes the duty of each nation to see that its people are educated to the same ultimate perception; and specially does it become the duty of that nation which seems appointed by the Divine order of things to become the central power of all the rest to push its influence and the genius of its institutions abroad and into every nation. A mere passive acquiescence in this Divine appointment will not suffice; an active and positive acceptance of the mission, and the faithful and persistent performance of the great trust, is required.

When the people of this country shall rise to a true and competent conception of the responsibilities of the position assigned it in the order of the universe, the present system of things will undergo such rapid transformations as no revolution ever yet accomplished, and to which the destruction of the Roman empire by the barbarians can alone compare in magnitude. By that the dominion of the world was wrested from Rome; by this that shall come, it shall be restored to that country of which Rome was the Divine prophecy. Personal, sectional and national motives will be sunk in oblivion, and such governing rules of action will obtain as shall bring the world into intimate, harmonious and Divine relations, such as will know no Jew nor Christian, Mohammedan nor Pagan, but one general and acknowledged brotherhood of man, flowing from the common fatherhood of God.

[Editorial from the New York Herald of May 27, 1870.]

WOMAN'S IDEA OF GOVERNMENT.

The public have, during the past few months, been interested and perhaps edified by the ideas and impressions put forth by Mrs. Victoria C. Woodhull upon the broad, general subject of human government, as well as by her subsequent nomination of herself as a candidate for the Presidency in the election of 1872. The articles in which she has announced these views and purposes have from time to time appeared in the _Herald_, and to-day we present a further communication on the question of the "Limits and Sphere of Government." It is evident Mrs. Woodhull is imbued with at least one very sensible idea, and that idea is one which it would be well for large numbers of aspirants for public positions to emulate—viz., that fitness is the first prerequisite of qualifications entitling the seeker to enjoy the position sought for. This it is, doubtless, which has led her not only to study and perfect herself in the nature of the functions she seeks to exercise, and their effect, but, in the honest belief that she does understand the question, to give her opinions to the people, that they may judge of her ability and the correctness of her views.

At the same time it is somewhat difficult to see what good will come out of this particular Nazareth. Mrs. Woodhull offers herself in apparent good faith as a candidate, and perhaps has a remote impression, or rather hope, that she may be elected, but it seems that she is rather in advance of her time. The public mind is not yet educated to the pitch of universal woman's rights. At present man, in his affection for and kindness toward the weaker sex, is disposed to accord her any reasonable number of privileges. Beyond that stage he pauses, because there seems to him to be a something which is unnatural in permitting her to share the turmoil, the excitement, the risks of competition for the glory of governing. There is therefore but one position that may be taken in considering the aim of this ambitious lady, and that is that, perceiving and fully appreciating the natural obtuseness of man, she has boldly put herself forward with a view to wearing down these scrupulous angles in his sympathetic character and nature, and that she will, after all, be content with the knowledge that she has done her full share in educating him for the new order of things which shall supervene when woman, in all matters, has equal rights and duties with him.

LIMITS AND SPHERE OF GOVERNMENT.

[Revised from the New York Herald of May 27, 1870.]

MRS. WOODHULL'S LATEST EPISTLE TO THE AMERICANS—"THE LIMITS AND SPHERE OF GOVERNMENT" CONSIDERED FROM A FEMALE POINT OF VIEW.

[In the following communication Mrs. Woodhull, whose former essays on political matters have been published in the HERALD, considers the question of government with special reference to the system under which we live in the United States:]

Having in "The Tendencies of Government" traced the rise and fall of nations, and found that from earliest historic time to the present, there has been a continual grasping for universal power, and a constant failure to maintain the extent of control actually reached; that the systems through which universal control was sought were too imperfect to admit of support for any great length of time over an extended area of country; that the general order of the world seems to indicate that universal government will become a fact, and that the United States shall be the seat of such governmental power, we may now come to consider what control a government must be invested with in order that it shall at all times meet the demands of the people and the times, and therefore be continuous while becoming universal.

It is predicated that government exists by the consent of the governed. While this is nominally true, it virtually contains but an undeveloped germ of truth. In no country as yet does the government exist by the consent of the governed. In this country least of all does it apply, though superficially it may not so appear.

Government is universal. All things in all the various kingdoms of nature are the objects of governing laws which form the subjective order of the universe. In all natural government the relations between the governing power and the powers governed are always well defined, while the requirements of the governed are always met by requisite modes of administration. Each coming demand falls into some common method of being answered. Thus, in the greatest conceivable diversity of conditions, are found the fewest and simplest laws of control. Rising from purely material to the more refined powers of mind, represented only in the human, a new phase of development springs up. Being an individualized power within itself, the human family represents the divine power that controls the whole, and in this relation fashions its governments according to the limitations of its acquired standard of wisdom, which must always necessarily be imperfect in comparison with the common laws of the universe, in the same proportion as human wisdom is imperfect when compared with divine wisdom.

The world of mind has now arrived at an age and corresponding development, which begins to comprehend the general laws of the universe, and to understand their great simplicity and perfect adaptation to all things under them. Seeing that such a perfect system of government exists throughout the universe of matter, the inquiry is beginning to be earnestly made, why the universe of mind cannot be controlled by equally simple and general laws and systems of administration. Seeing that changes are never necessary in the common universal laws, the inquiry is also beginning to be made, why the laws that govern society cannot be so fashioned after the laws of nature as not to require the constant remodelling now necessary when changes come, in the circumstances required to be met.

The solution of the difficulty in which the mind becomes involved when considering these most serious questions, seems reduced to a single proposition—that all strifes, difficulties and controversies regarding government and its administration, arise from the fact, that the governing power is not general but specific in its operations, or that the powers governed are not subservient to a

common law of control. This is still more clearly perceptible if the question of “reserved rights” on the part of any of the governed is considered. No individual can have a reservation that militates against the general welfare of others, or the whole, without specific laws to sustain him in it. If no individual can have such special reservation, no number of individuals less than than the whole, can have reservations without specific protection. Therefore no city, county, State, or number of them, less than all cities, counties and States forming a consolidated union, can hold in reserve any rights or privileges that do not contribute to the general welfare of the whole, without sooner or later coming into conflict regarding them. This theory of reserved rights was pretty forcibly, logically and effectually refuted by the late war; so must all such reservations be equally well refuted before permanent peace, harmony and prosperity can be expected to flow from government and it remain permanent.

Analytically and philosophically considered, government exists for the general good of all the governed, in which individual rights and privileges can find freedom and justice without conflict. All systems that exist upon a less comprehensive basis than this must eventually be swept away. All parts of systems that conflict with the general fundamental propositions in which they were based and reared must be expunged, so that administration can be in perfect harmony with profession, before it will be possible for general good to flow from administration. The fundamental propositions upon which this government professes to rest—that all men and women are born free and equal and entitled to the inalienable rights of life, liberty and the pursuit of happiness—are in accordance with the general order of the universe below man, and are therefore of the highest possible authority.

That all are born free is a proposition that no one can question; but this freedom is general to all, and does not refer to the individual, nor entitle him or her to push his freedom so as to encroach upon the same freedom guaranteed to every other individual. Therefore, individual freedom is merged in, and is a part of, general freedom.

That all men and women are born equal is another strictly philosophic proposition that can never be refuted by the concurrent scientific truth that no two of the whole are born alike in every particular. Equality, in a philosophic sense, does not imply similarity or even likeness; one thing may be equal to another, or a number of others, and still be unlike them all. A pound of feathers is equal to a pound of lead in gravitating power, but the lead does not resemble the feathers in any respect; hence, equality does not presuppose likeness.

The pursuit of happiness is an additional common right, naturally resulting from freedom and equality, and which can be prosecuted in any direction that does not interfere with the general pursuit of it on the part of the whole. From this analysis of inherent rights it would seem that it should be the sphere of government to maintain such freedom and equality, and thus guarantee to all and every the pursuit of happiness, and to protect them therein; and, co-relatively, that the limits of government should be nothing less than the circle that will permit such fatherly—such motherly—control.

It will scarcely be questioned by those who accept the evolution of government as a common law, that the government of this country, as a system, comes nearer being an exponent of the philosophic limit and sphere than that of any other country, though it must be confessed that the practices under it belie its fundamental principles. So much is this true, that, while it is safe to assert of the system that it is the best of all, scarcely one can be named wherein so great distinctions obtain between the intentions of the system and the effects obtained by its administration. This follows because, having asserted fundamental principles of freedom and justice, the lines of policy pursued have not been shaped by them. The principles have been lost sight of in the pursuit of party and personal or sectional policies, so that the government is no longer an exponent of principles, but rather of the persons, parties or sections which have raised themselves above principles as authorities: hence the government has limitations put upon the operations of its principles, and becomes thereby inconsistent within itself.

All the corrupt practices that are prevalent in the various parts of the governing process are possible only because the professions and practices of government are not in harmony. The professions of government relate to principles; the practices to its limits and sphere. Therefore, in the present article, the practices will be dealt with. In dealing with them it will come within the intended limits to examine the machinery by which government is administered, and to determine what movements within the body of society should be under its general control, so that all its movements may be made in harmony. Were any other branch of government than that relating to society being examined, its limits and sphere would be found so plainly determined there would be no possibility of even apparent departure by the governing control from them; for in all these the divine power is that control, and consequently is perfect. In society, the divine power, though the controlling element, is maintained over human minds, which are finite and imperfect representatives of the divine power, and are thereby incompetent to so arrange and order subservient circumstances, that harmony shall be the only result of the combinations formed to secure consecutive order.

The government of this country is selected for analysis because, as a system, it is the latest production of the social order of things, and, consequently, the highest in the scale of evolution. It represents a greater “coherent heterogeneity” in its construction than any other, and its “constituent units” are more “distinctly individuated,” which demonstrates that it is the highest order of government yet attained on the globe. The fault in its construction is, that the powers of the constituent units are not harmoniously related to the central power, nor to each other, discord being the natural consequence of such inequality. Though the constituent parts of society are in themselves imperfect, their relations to each other and to the governing power may be so well defined and regulated that their imperfections shall not have power to mar the harmony of action proceeding from the central power. And this is the point which is sought.

LIMITS AND SPHERE OF GOVERNMENT.

[Revised from the New York Herald of June 4, 1870.]

GRAVELY IMPORTANT QUESTIONS CONNECTED WITH GOVERNMENTAL ORGANIZATION AND ITS ADMINISTRATIVE DEVELOPMENT, AS VIEWED AND REVIEWED BY ONE OF THE FIRM OF FEMALE BROKERS OF WALL STREET.

There are a variety of operations, natural and artificial, by which the proper limits and sphere of government may be illustrated. It is desirable that some of them be presented, so as to convey a correct idea of a perfect controlling power, which bears the same relations to the parts controlled as government should to the people under it.

The cotton mills of New England are good artificial representatives of government. In them all the various parts are compelled into unity of action by the controlling power evolved from coal or transformed from water. The crude cotton is first taken and freed from all foreign substances by “the picker;” the pure remainder is then formed into a homogeneous mass by “the cards;” this mass is then divided and subdivided into the different degrees of heterogeneity required, and these are more distinctly individuated into “the webbing and filling” by “the jacks and mules,” and are then reunited by “the webber and loom” into cotton cloth, the ultimate result. Every part of this process forms points of resistance more or less easily compelled into unity of purpose. Every bobbin, spindle, shuttle and card are so many different experiences which are required to be gone through with before the result can be reached, while all parts of the process are going on at the same time. The power is the government; the operatives its administrators; the various pieces and parts of the machinery are the people working in the several parts of the process; the cloth is the attained civilization, while the different degrees of fineness are its progressive steps.

Thus it should be with human government. It is the power resident in the central part which should control all the processes by which the people are guided to produce the ultimate result. It should be of such character as to take the people in the homogeneous mass, and, by picking, carding, spinning and weaving, compel them into a unit of action for divine use. Every operation in nature, if analyzed, presents the same process and similar results. A central power competent for its purposes, through various means and avenues, controls the materials into perfected productions, each one of which is perfect of its kind. The sphere of this government is to produce the legitimate result; and its limits are only bounded by the necessities of the power that the result shall flow; but flow it must and does always.

It is then predicated, that a power, competent to produce harmony in that over which it reigns, must be sufficient to control all the different parts to one end; whatever individual or combined points of resistance may be raised to its edicts must yield to the general purpose, even to the extinction of their resistance. It is necessary, therefore, that the governing power must be invested by the governed with the necessary control, to compel them into harmonious action, so that no antagonism may arise, to divert the tendency to unity of purpose. It must not be supposed that a self-constituted, absolute power is argued for; but this power should be one fashioned and organized by and with the consent of the people, who, knowing their weakness and acknowledging it in their sober and wiser moments, shall recognize the necessity of it, to compel them, if need be, to act with the general whole for the general good, even if it seemingly militate against their individual good, and which shall be of sufficient strength and diffusiveness to regulate all the movements within the body of society.

We will now proceed to the analysis of the various operations of government, to find to what the inharmonious relations between the governing power and the resistance are attributable, and thereby be able to determine the required remedy. Wherever this may lead, whatever “infallible” political dogmas it may destroy, or cherished forms and privileges disprove, it will be pursued as relentlessly—unmercifully if you will—as the crucible and the flame proceed to disorganize material compounds and separate their constituent elements into the poisonous, the nutritious and the useful, that the former may be put away and the remainder

appropriated to promote the general good.

Government has its centre and its circumference. From its centre its power is distributed to its entire circumference, measuring and shaping the various channels through which it flows, into such form as permits harmony in all its parts, and, having spent its positive force, is then returned to its centre. This centre and circumference must be the perfect body, every member of which must not only bear its proper relations to all the other members, but must be in such accord with them, as to permit the uninterrupted flow and action of the power by which the whole is bound together. No individual member of it can say to the body itself, “I have functions and rights peculiarly my own, which, if they are not such as your general power can recognize as contributing to the general good, you cannot interfere with.” The member, in becoming such, merges its function and power with the general functions and powers of the body. By consenting to become a part of the body it gives up special sovereignty over itself and becomes a part of the general sovereignty. By adding its life and power to the body, it increases the sum total of its life and power and receives its portion of the aggregated and assimilated mass. Its parts and functions must change—if change is required—so that the power distributed to it by the general power can perform its mission in harmony with all its other parts. Like the body human, the body corporate must be under one governing power, while each part is different in form from all other parts, and performs separate—perhaps distinct—functions. The eye may not say to the ear, nor the hand to the foot, “I have no need of you,” for each and all, are alike dependent upon a central part for existence, while the central part could not itself exist without the surrounding and distant parts. The very nature of the compact is, that each and every part is joined in a system of mutual and reciprocal interdependence, to which general system no member can set up for itself any system peculiarly its own, in contradistinction or opposition to, or to interfere with, the general system.

The government of any country, originally, is a compact among a certain number of previously separate or unorganized powers, by which they merge and consolidate into one power, or are compelled so to do. This power, so formed, is the governing power, which, while all parts have contributed to its formation, is in itself superior to any power that can be organized within its limits by any part of the originally consolidating powers. If at any time an opposition is organized to it, the result must either be, the reduction of the opposition or the destruction of the confederation. For a natural illustration the human body is again referred to.

If from any cause an opposition to the harmonious action of the general powers of the body be raised, a contest for supremacy is inevitable. If the bowels refuse to perform their allotted part in the general economy of the whole, a conflict ensues, and never ends until they are returned to duty or until they demonstrate that their opposition to the general administration is more powerful than its general power, and that the organization must be dissolved in conformity to this power. On the other hand, the general power cannot compel any of the constituent parts to conform to rules and forms not operative in the whole, nor to bear any inequality of any kind, nor to perform duty outside its special sphere. The governing power, though superior to all, must itself be subject to the common law of justice. Specialties of conferment or requirement are utterly inconsistent with a perfect form of government. The same rule of contributing to the general support, and in turn receiving appropriate sustaining power, must be uniform throughout the whole. Such a body, thus acting, be it human or corporate, is alone a healthy and harmoniously constituted power. All governments, to be able to contribute to the public welfare, must exist upon general similar principles and act by similar means.

It must again be observed that when several parts or powers are organized into one, no power less than the whole has authority therein; for, in consenting to the union at first, all absolute individuality is forever waived; the individual is no longer simply an individual power, but forms a part of the common power. Nor can absolute individuality ever again be maintained, except a superior antagonistic strength is developed, which demonstrates that the powers originally attempted to be consolidated were impossible of harmonious action—a natural and sufficient reason for dissolution. Tested by these propositions, what conditions and relations does the government of the United States, as a whole composed of parts, present? Does it form one homogeneous whole, the paramount interests of the parts of which is the best welfare of the whole? Does each and every part act in unity and harmony with every other part, and in turn yield to the preponderant authority of the whole, with that grace and dignity which bespeak unison of purpose and interest? If not, where does the difficulty find its starting point? Is it in the system by which the power was organized—in the interpretation of it, or in its administration? For this the Constitution must be referred to to find wherein, if at all, its organization is defective. If the conferment of power by the organization is complete, then it must be concluded that those who administer its organic force either fail to comprehend the extent of its application or to perform their duty in applying it.

LIMITS AND SPHERE OF GOVERNMENT.

[Revised from the New York Herald of June 19, 1870.]

ANOTHER LETTER FROM VICTORIA C. WOODHULL ON POLITICAL HISTORY.

ARTICLE IX. of Amendments to the Constitution declares that “The enumeration in the Constitution of certain rights shall not be construed to deny or disparage others retained by the people.”

ART. X.—“The powers not delegated to the United States by the Constitution, nor prohibited by it, to the States, are reserved to the States respectively, or to the people.”

SECTION 1 of Article IV. of the Constitution says, “Full faith and credit shall be given in each State to the public acts, records and judicial proceedings of every other State. And the Congress may by general laws prescribe the manner in which such acts, &c., shall be proved, and the effect thereof.”

SEC. 2.—“The citizens of each State shall be entitled to all privileges and immunities of citizens of the several States.”

SEC. 8.—“That Congress shall have power to provide for the general welfare of the United States,” which last is tantamount to saying, the general welfare of the people as a whole.

It seems from these quotations, made in inverse order, that it was the intention of the framers of the Constitution, to make such provisions as would permit and compel harmonious action throughout the States, but that subsequently it became a part of party policy to maintain that the States had rights reserved, and while not defining what these rights were, to declare that such as were not distinctly and positively delegated constituted this reservation.

Under this interpretation it is possible for serious difficulties to arise between the general government and the States, as they have. It seems from the general tenor of the original Constitution that these amendments are nugatory, because the inference to be drawn from them is inconsistent therewith. One of the most prominent, as well as the first declaration, is to the effect that nothing shall exist in any State injurious to the general welfare of the whole. While it is within the scope of Congress to determine what is for or against the general welfare of the whole, no State can set up its rights against such judgment. When it is further made the duty of the United States to guarantee a republican form of government to every State, and to protect each State in such against all others, there can be no limit set upon the general powers of Congress.

The only fault, if fault it may be called, in the original Constitution, lies in this—that while the power to do is vested in the United States, it is not made an imperative duty to perform, though the duty is to be inferred by the vesture of the power. In failing to exercise this power in its fullest sense and to perform this inferred duty, lies the cause of all the disturbances within the limits of the country.

We can now proceed to the consideration of what duties Congress is invested with the power to perform, which have not been exercised, and which, being exercised, would contribute to the general welfare of the people, and thereby promote the public good. It will also be considered whether there are any additional powers Congress should possess which can be conferred, and which the Constitution neither directly nor inferentially vests. This consideration will proceed without regard being given to separating what comes within the limits already possessed from that which should be conferred.

First in importance, because of general application, stand the common laws of the country. Of these it is asserted, with the utmost directness and force, that when a general condition is to be provided for in the country, it should be the sphere of the government to make the same law applicable everywhere, so that the citizens of the United States shall, at all times and places within its limits, be subject to the same controlling and guiding rule. There should be no such possibility as an Indiana divorce under Indiana law, differing so much from those of other States as not to be recognizable by them. There should be only United States divorces, under a general law that could not be questioned anywhere, and by which the parties to it, should stand in the same relations to each other, in whatever part of it they might chance to be, also in such relations to every one, that they may remarry without becoming liable to the charge of bigamy.

Within the last few years, many States have found it necessary to so reconstruct their general systems of law as to cut off all special legislation. This course is eminently judicious in every respect it can be viewed, and has proved excellent in practice, by relieving legislation and procuring uniformity. If this is a desirable result, so far as a State is concerned, why should not the application be made general for the United States, with prospect of proportional benefit? All people would then be subject to the same rule of action and responsibility. To illustrate: A State has a general law under which joint stock and other companies can become incorporate. Before this, each proposed company was obliged to make direct application to the State government for an

act of incorporation. After it, any proposed organization could become incorporated by conforming to the regulations prescribed, and thereby obtain all the power that could be conferred by the Legislature direct.

No one having knowledge of the tedious processes of legislation will question the advantage of this general law, both as regards legislation and the people. This admitted, it must be further admitted, that the advantage would be still greater, were this a general law of the United States, applying in every State, instead of a mere State law, with the probabilities that each State having it would provide different steps and regulations, so that a person familiar with that of one State, finds he knows nothing of it in the State he removes to.

The same line of reasoning applies with more or less force to every branch of legislation. Especially is it pointed regarding the Criminal Code, for here very great distinction exists in the several States. The penalty for a specified crime is scarcely the same in any two States; while some have abolished the taking of life for life, others still imprison for debt, which shows a degree of divergence entirely incompatible in a country that professes unity of purpose and practice. In civil practice it is utterly impossible for the most studious and profound jurist to acquire and retain accurate knowledge of it, in even a small proportion of the States. Every lawyer can testify to the difficulties he encounters at every turn when the laws of another State have any bearing in the case he is engaged upon.

Some States require that deeds executed in another State for property within itself, shall be acknowledged before a notary, while another requires a commissioner of deeds; and still another the certificate of some Court of Record that the notary is duly appointed, &c. The difficulties that arise from this condition of things are of such magnitude as scarcely to be conceived of by those who have never experienced them; nor can they be adequately presented in the limited space of this article. It is, however, held to be apparent, that if a general bankrupt and election law is to be preferred to thirty-seven different ones, general laws upon all other subjects are also preferable. It is a logical conclusion that the “public welfare” would be promoted if Congress should pass general laws for the whole country, to cover all cases and causes that are general to the whole country, leaving for the States such legislation only as can have no application outside of their individual limits.

It is not surprising that well instructed jurists of foreign countries have no faith in our existence as a consolidated nation. They argue, that it is impossible of a country containing so many internal sources of discord and differences. “A house divided against itself cannot stand” they hold to equally apply to nations. If this has stood thus long and prospered, it by no means follows that it will always stand and prosper; but the inference is, that sectional interests will be the source of continual disturbances and revolutions, until some great sectional interest shall become powerful enough to separate itself from the rest of the country and to defy its power successfully. In view of that consideration, should not the attention of Congress be called to the fact that it is its inferred duty, at least, to enact all laws that will promote the public welfare? And to this end it should inquire how the public welfare is suffering from the neglect thus far practised, that the remedy may be applied.

If it is found that its power under the Constitution to remedy such evils is doubtful, amendments granting it should be at once proposed and submitted. Whatever opposition there might be on the part of present State Legislatures and officials the people will welcome any measure looking to the eradication of the cause of internal agitation. It cannot be that patriotism is to pass away entirely, though it appears to be nearly submerged by the rising tide of individual selfishness. Let it arouse itself and consider whether there be not room for exercise in the direction indicated, and whether it is not better to prevent disaster than to repair damages. The example of Louis Napoleon is an excellent one to follow. Nor should patriotism be blinded by the mere name of freedom and justice, sounded so loudly to cover the deformities practised under their shelter.

In many directions, this is eminently an analytic age. Let the fruits of government be submitted to the crucible. Many of them would be found not only hollow, but basely deceptive. It is well enough to cry peace when war rages, but the crying will not bring it. It is well enough to laud the freedom of the land, but why not make the direct inquiry to find how much of it is real, and how much is fancied freedom, not to say genuine slavery? It is well to assert that justice holds sway everywhere, but those who have had most occasion to find it, must hold their peace lest the fair delusion be dispelled. Let the peace that is cried, the freedom that is lauded and the justice that is asserted, be subjected to the test of analysis, that it may be really known what principles enter into their composition. It is much to be feared that when all the dross and foreign substances are separated, and the pure residuum only left, its proportion to the mass submitted would be lamentably small. Still let us have the analysis.

LIMITS AND SPHERE OF GOVERNMENT.

[Revised from the New York Herald of July 4, 1870.]

THE FIFTH PART OF MRS. WOODHULL'S DISQUISITION ON GOVERNMENT—INDIVIDUAL ENTERPRISE AND ITS DEVELOPMENT AS AFFECTED BY GOVERNMENT.

Individual enterprise, especially among Americans, has produced the most wonderful results. Very much of the advancement of the country is directly attributable to it. Great minds have been obliged to operate singly and alone to develop their inspirations, ideas and conclusions. Thousands possessed of comprehensive principles in a semi state of application have sunk with them into obscurity for lack of appreciation and support. In the infancy of the republic, before it was possible for any to catch the idea of its grand destiny, it was not to be expected that any great or general system of interdependence between the government and the people should be adopted. There was a general fear of everything that did not seem to promote that individual freedom which seeks no harmony with the greatest freedom of the whole, while no regard was paid to any philosophic relations of the individual to the whole number of individuals represented by the government. This was intellectual individuality, lacking the harmony of wisdom.

It came after a while that the great enterprises demanded by the rapidly increasing growth of the country could not be conducted by single individuals, and numbers of them combined to carry them out. Rapid means of transit began to be developed, which in many instances redounded to the pecuniary benefit of the company prosecuting them, but always to the general interest of the whole, both as a people and as a government. On the contrary, many enterprises which have proved equally beneficial to the country have ruined those who projected them. Thus the general welfare has been promoted by the sacrifice of individual interests. Especially has this been true of the great system of railroads that binds the nation together with bonds of iron, too powerful, it seems, for any sectional interest ever to sever.

Internal improvements are eminently a legitimate branch of the general government. They are not for the benefit of individuals or sections, but for the benefit of the whole. So true is this that a seemingly purely local government cannot confine its benefits and uses to the section it is located in. Its influence permeates the very extremes of the country. A railroad connecting two cities in the same State may be built. At first glance this would be declared simply and only of benefit to the localities it passes through. But upon close scrutiny a variety of ways develop themselves that must be advantageous to thousands, residing in all parts of the country, and to the government itself. It therefore conduces to the public welfare and convenience in a much more general sense than to sectional or local good. It is therefore entitled to the protection of the government, whose duty it is to look after and promote the interests of the public. Is it entitled to anything more, or does the full duty of the government begin and cease with simple protection?

Continuous railroad connections exist between Maine and California, between Minnesota and Louisiana, which have been built by private enterprise, and are still maintained and conducted by combinations of private enterprise. These, with their connections, form a net work that penetrates every section of the whole country, all parts of which system are conducted as nearly as possible, considering the variety of management, with regard to the harmonious working of the whole as a general railroad system of the country. The representatives of the several roads meet and arrange terms of transfer and connection, first, to accommodate themselves; second, the public which patronizes them (be it especially remembered that the public welfare is always secondary); and thus it comes that that which is made the duty of the government to guard with jealous care is subserved to the interests of a company of incorporated individuals, whose profits, drained from the productive interests of the country, amount in many instances to an enormous per cent per annum upon the original costs of the enterprises This is not the greatest good to the greatest number. It is the greatest good to the smallest number at the expense of the greater number. The public is hoodwinked into the toleration of their extortions by fictitious arrays of figures, and by the increase of the "watering" of their capital stock whenever an eight per cent. dividend will not consume their unexpended balances.

Again, there are railroads of great importance to the general public whose earnings are not sufficient to make any returns to stockholders, scarcely sufficient to meet current expenses, and yet the public welfare would not permit of their discontinuance.

The same line of policy that controls the postal service should be pursued by government in regard to railroads. None now think of intrusting that very important department of the government to private enterprise. Is the transportation of the public itself of less vital and general importance than its thoughts and wishes are, that it should be obliged to rely upon private enterprise to accomplish its welfare, and to obtain it be subject to its extortions? The custody of transportation of all kinds by government would insure regularity, harmonious operation, safety and dispatch, at minimum cost, to all whose pursuits, interests or comfort, incline or compel them to its use. If the sphere of government is to be determined upon principle, and it is the true principle for the

government to conduct the postal service, to the end that the public welfare be subserved, then the same principle determines that railroads and telegraphs should also be conducted by government to the same end.

The time was, when it was necessary to the general good for the government to guarantee protection and even assistance to enterprises that should introduce these improvements into the country. The country needed them. Government, not understanding its true relations to the people, failed to provide them. Private enterprise, more sagacious and more perceptive of the actual demands of the age, stepped forward, and, taking advantage of governmental supineness, developed the true greatness of the country. The time has now come, and the government is in position and understanding, to not only guarantee all needed internal improvements to the public, but also to take charge of those already existing, and to conduct them in the interests of the people.

These improvements are not patents that should forever remain hereditary charges upon the industry of the country. They are granted privileges, made by the government to promote the public welfare, and not for the continuous private gain of wealth and power. Let a limitation be put upon these patented privileges, so that the public good may be still further promoted. Let government purchase what are already in operation and construct others, as demanded, and conduct them all under one grand system, to subserve the interests, necessities and comforts of the people, which it is its duty to provide for, even if in exceptional instances it be at the expense of the public, as in some instances it is in sparsely populated districts regarding the postal service. Let the same rule of action that governs this service be applied to telegraphs, railroads and all improvements that are public in their character. Let the present owners and conductors of them become the servants of the government and the people, instead of remaining, as now, their masters, thus forcing them, by the only possible way, to comply with the interests and demands of the general welfare.

Besides, these gradually consolidating interests are becoming too powerful and selfish to longer allow of the government or the people regarding them with indifference. Even now they control a deal of legislation by the power they possess. Unless soon dispossessed of the means of increasing their power and influence, they will become greater than the government, and even dangerous to liberty. The national banks are powerful enough to feel they can dictate to Congress. What might not a grand consolidation of railroads, representing thousands of millions of dollars, be able to do, if left to present tendencies? This is a matter of most serious import, which is tending to a despotism more intolerable than that exercised by any of the monarchies of the Old World—the despotism of capital over labor.

This despotism is making the productive interests of the country utterly subservient to the power they have created, fostered and protected, which should forever remain their servant instead. These improvements are demanded by all the growing interests of the country that express themselves through commerce between the several States, and it is the duty of Congress to “regulate” them. It has the power. The remedy is required. Let it be applied, and at once, so that the greatest and most beneficial of all the many systems of internal improvements any country possesses, both for the country as a whole, and to the comforts of the people as individuals, may be conducted and extended in accordance with the interests and demands of the public welfare. Nor should there be any outcry raised against the purchase and control of railroads by government, as an unwarrantable interference with private rights. There are no such things as private rights when the public good stands in question. If the public good demands a new street through the most densely populated part of the city, the property of private citizens is condemned to its use, and damages assessed, from which the individual has no appeal. The same rule must apply to all property that the public demands for the promotion of its interests, telegraphs and railroads not excepted.

LIMITS AND SPHERE OF GOVERNMENT.

[Revised from the New York Herald of July 11, 1870.]

MRS. VICTORIA C. WOODHULL’S CONCLUDING CHAPTER ON THE SCIENCE OF GOVERNMENT

[The following is the concluding chapter of the essay on government, its aims, sphere and tendencies, by Mrs. Woodhull, the female candidate for the Presidency:]

There are no circumstances existing within the range of government which are deleterious to the conditions among which they are found that do not come within the sphere of its control. If it were attempted to enumerate all such conditions, a very large proportion existing would come in for mention. Special reference will be made to such only as are represented by crime, indigence, helplessness and perverseness. While government has its duty to perform regarding all these, in their relations to society in general and the public welfare, it must not be lost sight of that they form a part of the general public, and, as such part, it has a duty to render even to them and to the relations they sustain as individuals to other individuals.

The criminal is not only the son and brother, but often the husband and father. Though he may have, by some act, forfeited the guarantee of liberty government extends to the people, he has not thereby sundered family relations, responsibilities and duties. It is the duty of government to foster these, while protecting public welfare by preventing the criminal from pursuing his course of individual freedom at the expense of the freedom or happiness of other individuals or the public. In this view penitentiaries should not be what they are, but should be changed into vast workshops, where the convicted may labor at some not altogether distasteful employment, to the same end that he should labor when free. The theory of punishing crime is not all that should be taken into consideration regarding the criminal. As now practiced it is exceedingly doubtful whether the State does not do the individual greater injustice than he has done the public. The State should pursue such a course as is perfectly clear from injustice, such as can conscientiously be held as committing no crime against the criminal. To render to him what and only what he has rendered another is maintaining the old Mosaic rule of “an eye for an eye,” which in these latter times should be obsolete. The world has risen from the condition of Mosaic times by the experience of thousands of years. Fear was the only controlling power then. Should it be so now? Prevention is better than remedy; besides, there is no such thing as remedy for crime already committed. The criminal can by no possible means—nor can the State—undo the wrong. Reparation in most cases is impossible, but should be rendered, wherever possible. It becomes, then, the chief duty of the State to prevent the recurrence of wrong by putting such restraint upon those who are inclined to it as will effectually prevent their inclinations finding expression.

Supposing that all living persons who have ever committed any infringement upon the rights, liberties or privileges of others of sufficient moment to warrant preventative means being applied were restrained from mingling with the public, what would be the ratio of decrease in crime? These persons have trespassed upon the public welfare and it must be protected from further trespass. It is the duty of the State to see this done. At the same time the means of prevention must be such as shall not encroach upon the culpable one’s rights further than such prevention actually requires. As a member of society he has forfeited to society, to a certain extent, the freedom of expressing his privileges and rights as an individual, by the infringement upon the privileges and rights of another individual, also a member of the same society; and for this, society is in duty bound to restrain him. It only requires that the present universally adopted theory, that crime is against the people and not the individual suffering, be carried to its legitimate sequences to teach the proper limitation to this restraint. Having arrived at that, it remains for the State to concede every other individual privilege to him.

It should be his right and privilege to labor and receive its full recompense, to which the State should have no right, further than the cost of his maintenance. The profits should be given those dependent upon him, or should go toward reparation for the damages done by him. He should have the privilege of amusement, should have access to a public library and the daily news. His whole restraint should be made as nearly as possible analagous to the every-day life of a useful citizen. He should no longer be the condemned criminal, but the member of society whom the public welfare requires shall be restrained from following the freedom his proclivities indicate.

There is another class of individuals who, either from circumstances beyond their control, from indolence, from incapacity, from settled habits or from perverseness, do not perform sufficient labor to maintain themselves and families in a condition that renders them useful members of society. Society suffers more or less from all the different representatives of this class. They must live, and society must, in some manner, furnish the means to them of living. If it is not earned, it is begged or stolen. There are those also who, being too honest to steal and too proud to beg, suffer untold privations. All who would cannot obtain remunerative occupation, or that which they are suited to perform. To all of these as members of society, as a part of the people, government owes a duty. Society, of which they are a part, owes them the necessities of life, even if it be compelled to force them to earn them. It cannot be made the duty of individual members of society to look after the amelioration of these conditions. It is a general condition growing out of the relations of all its members, and hence becomes a governmental function, not only so far as they, as a class, are concerned, but also to protect individuals of other classes from being made to bear the burdens of them, either by voluntary contributions or from the impositions of beggary and theft. Every one who has attained proper age, and is possessed of moderate health, is capable of performing sufficient service to support him or herself, and by so doing is a useful member of society, because contributing to the sum total of its productions. If he cannot obtain employment, society should supply it to him. If he will not labor, society should compel him. If he cannot labor, society should maintain him. Were this practice once instituted, the dens of infamy and vice, the sink-holes of crime and disgrace, the pest-houses of disease, and the crammed-to-suffocation attics and cellars of our large cities, would be emptied of their occupants, and they be made useful, instead of, as now, iniquitous members of society. They are a dead weight society has to carry. It is a duty society owes them and itself to compel them to assist in maintaining its general progress. The same principle that applies to the criminal should also include them. The general influence they exert upon society is

even worse than that of the downright criminal—for where the criminal is one they number thousands. If it is necessary for the interests of the people that he who steals a hundred dollars should be restrained of his liberty—and it is the sphere of government to do it—how much more would it be for its interests to transpose these leeches upon the vitality of society into producing members of it? As a subject wherein the public welfare suffers, it is strictly within the sphere of government. Other citations of unprofitable members of society could be made, but sufficient has been alluded to to indicate the general limits and sphere of government when considered philosophically. The evidences of a perfect government must not be sought among the most powerful and useful members of society, but among the very lowest classes. A good government can have no classes so low in the scale of development or use as to be detrimental to its interests. And here is the test of governmental perfectability. If the United States, as a nation, occupies any superior or conspicuous position in prophecy which is to make it representative—if it is the point around which consolidation into universal government is to begin, and from which control shall revolve until the world is its object—it becomes the imperative duty of our statesmen and legislators to extend the sphere of government until its limits are bounded by nothing that is detrimental to the general welfare of the people. Such government, and such only, can be enduring while becoming universal.

VICTORIA C. WOODHULL, 44 Broad Street.

THE PRINCIPLES OF GOVERNMENT.

NO. I.

Government being an organization of power, and power always presupposing action, motion, it becomes a matter of the gravest importance to a people who are formulating a government that they should lay hold of the highest sources from which action can spring—that is to say, as all action is the result of some prime motor power, to have action which will proceed in perfect channels, producing harmonious motion, it is primarily essential that the motor, or moving or controlling force, shall be of that character which in expression will move majestically yet sympathetically against all opposition, always having in view the fact that the presence of low forms of any development is detrimental to all higher forms with which they come in contact, either directly or through exerted influence.

It has previously been found that the deductions which are to be drawn from a complete analysis of all the tendencies which governments have exhibited during the historic age of the world, conform to the propositions of the highest form of religious conviction, which is, that God being the common Father of humanity, that humanity must be a common brotherhood. Consistent with this the tendencies of government are found to have ever been to one common form. If these propositions grow out of the fact that the principle of unity is at all times operating to bring about a perfect expression of itself, through humanity, the legitimate deduction is, that the time will come when its ends will be accomplished, and that that time will be when humanity has risen into a complete recognition and acceptance of the fact that they are all children of one common parent.

Principles never change. They constitute the basis of creation, the forms of which are constantly changing under the influence of the application of the same power. The same force which caused the matter of which this planet is composed to first assume its orbital position and motion, now causes the various parts of it to exhibit the almost infinite variety of manifestation which is now presented. The same power that was exhibited in the construction of the original rocks, is also exhibited in the construction of the sweetest, most fragile flower. The evidence of evolution—progress—being, that from the rocks the flower has been produced. Ascending to the animal kingdom, motion, the result of power applied to matter, was found manifesting itself in the simplest of organic forms. There, as in the previous periods, it continued its constructive workings, until the perfect animal form, man, was evolved.

In the strictest examination which can be made into the power which controls, there can be nothing detected which would seem to, even indicate that there is anything outside of, and superior to the contained life, to which to attribute the direction the form takes through which life is manifested. If this be so, the principles which underlie the physical universe are but names for this inherent power, which cannot be attributed to any power less than the Source of all power. Manifested principles of action, then, which relate to matter, may justly be considered as the perfect operation of divine law through the physical universe.

It becomes resolved to this: that the power which is the compelling principle of all action is at all times the same, but that it manifests different results, as the channels through which it operates are different Thus, the motion of the atmosphere over the surface of the ocean exhibits power by the waves it produces; while the same power proceeding to land bends the forests and the

fields, verdure before it. The tiller of the soil involuntarily recognizes this fact, when he destroys all growths which exhaust the constructive power of the air and soil except the particular one he desires to further or perfect. He knows that to concentrate all the power upon this one, he must concentrate its expression in the form he wishes developed. If this process could be understood, it should be the ordinary rule in every department of the universe. All the power there is, should be concentrated into action through the most advanced, and consequently the most perfect forms—perfect forms always being those which are adapted to the highest uses.

Wherever this rule is generally applied by nature or man, the lower existing forms disappear, and in due time the higher fill the places they occupied. Thus, species of plants and animals are constantly disappearing from the economy of the universe, while new and higher are as constantly appearing. And it is to be specially observed, that where the new exists the old dies out. This law is also distinctly visible in the development of the different races and types of the human, all of which a universal tendency prophesies will ultimately be merged into one grand, all-comprehending race. The tendency to this condition was distinctly traced in the Tendencies of Government, and was held to be the basis for the conclusion, that, in its continuance, the condition named would be naturally and inevitably reached. It may be stated then, as a general rule, that the most certain method there can be to destroy the bad—the old—and to inaugurate the reign of the good—the new—is to attend to introducing the good in the most rapid and best manner, which will naturally live upon and sap the life from the old, which must necessarily pass away.

If a new race of humans is introduced among a race which is not possessed of that capacity which makes it possible for it to develop or assimilate to the new, it will most certainly die out. Such races are fixed types of the human, and their characteristics can never be merged among the general characteristics of the future common race of humanity. The North American Indians are good examples of this fixedness, and they will soon cease to exist upon the face of the earth; while the Negro is an excellent representative of the capacity of evolution and also of amalgamation. It is not to be lost sight of, that when the Anglo-Saxon and the Negro amalgamate, the direction the amalgamation takes is always from the black to the white, and never from the white to the black, which is positive evidence that the Negro will ultimately be entirely lost in the white races.

A mighty lesson is also to be gathered from observing the constructive process of the several kingdoms of the earth, each one of which is built upon the preceding and leads to the succeeding. The vegetable kingdom could not exist until the elements comprising the mineral had gone through their various processes of integration and destruction, by which vegetable life was made possible. The vegetable, taking up the process inherited from the mineral, began moving through the same cycle of advancement by which the mineral had made it possible, and it gradually merged into the animal; and so gradually that it can scarcely be decided whether some forms of life belong to the latter or to the former. The evolution of the animal, having ultimated in the production of the human, it is not to be inferred that there is nothing beyond the animal kingdom which is the fruit thereof, as the vegetable was of the mineral and the animal was of the vegetable.

Again, the vegetable world feeds from the animal—the animal feeds from the vegetable, which is the only source which furnishes living protoplasmic food, upon which the animal can alone exist. Humanity takes this protoplasmic dish either fresh from the vegetable or second-hand from the animal. It will thus be seen that everything which nature accomplishes serves specific purposes, and that when the supply is exhausted the demand ceases. If this principle is followed to its legitimate end, it will close in the life of the whole animal kingdom being merged into humanity, which will then feed entirely from the fresh protoplasmic dishes of the highly developed fruit of the vegetable kingdom.

These arguments are not pursued as a necessary part of the Principles of Government, but that the working of universal principles may be caught sight of and made use of in the endeavor which will be made to decide how humanity can best assist the operations of these principles as applied in its own government. Nature being ever consistent in all her movements in the several kingdoms, how shall “Mind” assist her in accordance with her own principles of operation, in establishing perfect channels for her powers to produce the perfect fruit of the animal kingdom?

In the Tendencies of Government it was found that all movements in government which have been made during the historic age of the world have been in the direction of universal control, the persistence of which course leads to the conclusion that it will be attained when government shall be based in those principles which, proceeding from a common centre, shall be sufficiently potent to control the entire circumference of humanity. The limits and sphere for such a government to exercise its power in, was found to properly extend to all matters in which the common interests of the public are concerned as against assumed individual interests, which would in reality be to the “greatest good of the greatest number.”

An exemplification of the natural working of a government founded and administered according to strictest governmental justice may be seen in the growth and in the maintenance of the life of the tree, which may be made to represent the tree of humanity. The tree is a complete community within itself; all its branches and twigs, even to the extremest distance, are dependent upon the same fountain for its controlling life currents that the parts nearer the base are. No single branch can maintain its life independent of the rest. Each separate one must draw its proportion of supplies from the same source and return the stream to its fountain when its demands upon it are completed. This power, starting from a common fountain, is delegated to the various branches for still further and more general distribution; but no branch can set up a distributing process for itself in opposition to the general process. If the branches had the power to set up processes of their own, the inevitable result would be inharmonies in the common order, which would work ultimate injury to all parts connected with the main body. Thus it is with a country. It must possess a common governmental fountain, and all divisions of it must be directly dependent upon the common fountain. No division can be permitted to set up special channels of administration for itself. Each must work in harmony with all others, and all be equally dependent and dutiful to the common head. In such and in only such can harmony prevail and life be continuous.

Having found, then, what the destiny of government must be, and having determined its proper limits and sphere for operation, it becomes still more essential and necessary that the true mainsprings of governmental power shall be recognized, for without this, government would still linger in its age of temporary resorts to get over the constantly arising contingencies of the times. When this recognition takes place, legislation will have accomplished its work, and the vast talent therein expended can be turned into the channels of governmental art. It is to attract the mind to the operation of general principles in nature that we have thus far dealt with the material universe. In advancing into the subtler department of mind, it cannot be for a moment supposed that an entirely new arrangement of principles lies at its base, any more so than that there should have been new rules of nature to introduce the animal or the vegetable. Instead of this having been, it is perfectly demonstrated that the same laws govern in each and all; that is to say, that the same principles of government control them all. Bearing this in mind, we now proceed to the consideration of the operation of principles wherein the human mind comes to assist nature in its strife for perfection, itself joining in the race.

THE PRINCIPLES OF GOVERNMENT.

NO. II.

It was remarked previously that Nature is consistent in all her operations throughout her entire domain; to which may now be added that the nearer the human approximates his rules and methods to those exhibited in the departments of Nature below him, the nearer will he approach to true rules and methods. Arbitrary and dogmatic formulas do not belong to Nature in her free manifestations, nor can they be administered in any of her combinations. In all the uses men may make of the elements of matter, he must comply with the laws of their existence: he cannot frame a law, and then command that Nature shall obey it.

Certain quantities of certain elements will combine and form a compound; but no other proportions of the same elements will combine to form the same compound, and in many cases they will not combine at all, unless certain fixed quantities are adhered to. Again, an effort may be made to unite two or more bodies, and they will be found to be incompatibles; that is, incapable of being united, because each has a stronger self-affinity than for any property existing in either of the other bodies with which they are brought in contact; but to these two or more bodies another principle may be added, which will produce the effect of uniting the whole. It is this principle in nature by which its elements combine and form all the various and diversified manifestations that are visible everywhere. These forms are none of them absolutely independent: they may, by their inherent power, attract other forms to themselves, or be by others attracted; the more complex and distinctly individuated ones being dependent upon those from which they spring for their existence; thus, as was before stated, the animal world is absolutely dependent upon the vegetable world for the protoplasm it must make use of to replace that expended by the animal economy. No animal can take the elements protoplasm is composed of and manufacture it; that process is alone the office of the vegetable world. And thus it is that a complete and infinite system of dependence exists from the lowest form of organic life to the highest; each is necessary to every other, while every one fills a special individual position of its own, and this is because they are all bound together by the same controlling powers or principles of action.

It is readily seen that the principles referred to are the same that are expressed by a common humanity, a universal brotherhood: one is a brotherhood of the elements; the other is a brotherhood of the ultimates of elements, of which mind is a product. Each kingdom has its beginning and culmination, and by the observation of their evolution we must draw the deductions as to what really governs that age of the world, and the special kingdom we find ourselves living in. The beginning of the mineral kingdom was when

simple elements began to unite to form compounds; which was when the cooling process had so far progressed as to allow of combination; this process of the uniting and dispersing of elements culminated in the production of the simplest vegetable life, and thus ushered in the vegetable kingdom. In this, again the same process of uniting and dispersing was gone through with that had characterized the mineral. It began as it did, and culminated as it did by producing the next higher, or the animal kingdom, the simplest form of which is a single unit of nucleated protoplasm. Upon this single unit the animal kingdom began to be built. The same process of integration and disintegration continued through countless ages and until a form was produced, which is the ultimate of form in the animal kingdom. This ultimate, man, is the perfection of form that protoplasm can produce, and hence is the grand ultimate of the process of elemental combination first referred to. No other or higher form is possible to be arranged from the elements that the earth is composed of. Therefore, all future advancement to perfection must be in the perfecting process in man, and therefore it is logical to conclude that the same law that governed the beginning, the evolution and the ultimation of each of the kingdoms that produced man, will also govern the beginning, the evolution and the ultimation of the different stages in the perfecting process in him; and not only in the perfecting process as a whole, but in each division of the perfecting process; and this brings us to that part of the process illustrated by government, and to the principles of government which are under consideration.

It will be observed that there is a perfect analogy in the process of evolution that is observed below man, and in that which comes of man. First, there was the elementary unit, which corresponds to what was the governmental unit—the family government. Next, and second, there was the vegetable division, which corresponds to the second order of government—the consolidation of families into tribes. Third, there was the animal division of the process, which corresponds to the amalgamation of tribes into nations. Fourth, there was man, the ultimate of the whole process, containing in him the elementary principles represented by all the preceding forms—in none of which were they all represented as they are represented in him—and he corresponds to the ultimate of the process of governmental evolution, the complete consolidation of nations into one grand nation, as man is the complete consolidation of all animal forms in one grand animal form. His form is the animal form, containing all animal forms. A universal government would be a national form, containing the form of all nations gathered into one grand form. Here it is that the analogy is complete, and Nature is consistent in all her parts and processes, at all times and in all forms observing the simple general principles which so unerringly lead her.

There is, however, one important addition to the processes in which man takes part, over those where principles apply only in the so-called material control. Below man there is nature only. After man there is art added to nature; and it is this power to administer to Nature’s processes, to assist in them, and to remove and replace obstacles to activity in higher channels, that distinguishes man from all previous formations, and which virtually makes him an assistant in the after and higher evolutions of mind, which have, until very recently, been generally considered not of material origin, but which science now demonstrates are purely physical results—are combinations in consciousness of consecutive manifestations of matter. Here we have the ultimate production of the ultimate of the animal kingdom, the mental kingdom, or the kingdom of ideas.

Science also demonstrates that ideas evolve after the same formula which all preceding processes observed, and that all new discoveries of ideas are not discoveries of existing facts, but that they are new truths evolved from preceding forms of truth; or, in other words, that they are higher forms of truth.

These relations are thus specifically stated, because in them is found the authority for man to make use of all things which exist, that by such use, higher purposes may be subserved and better general conditions obtained. As the gardener destroys all weeds and foreign growths about the vegetables he would produce, so must the gardener in ideas pull up, eradicate or destroy, all false or decaying ideas which sap the vitality from those he would have flourish; and this authority is the same—the authority of the higher over the lower, to the extent of individual freedom and within the limits of the general good.

Such is the province of art, and man, in whatever department of nature he operates, is the artist, adding to her beauties, which she can produce by her laws, those which the evolution of higher ideas proposes. Thus art utilizes and beautifies all that nature produces. Nature alone could never produce a Central Park, nor the perfection in fruits and flowers that is now presented to please the taste and gladden the eye. No one will question the right of man to make from nature the most of beauty it is capable of, nor to make it most conducive to all his natural desires. And here is found the basis for the authority from which it is analogically argued, that man has the right to practice as an artist in ideas. The position this artist in ideas should be assigned should be as much higher in the scale of importance as ideas are higher than crude matter.

Government being the most formidable director of ideas and the most powerful opponent of their diffusion, if they are not in channels it can operate through, its perfectability according to the highest existing ideas is a matter of the most fearful importance.

It is for this reason that so great importance attaches to the diffusion among the people of knowledge of the principles government should be constructed upon that its administration may be productive of the greatest individual, and the greatest public good, which it is possible to obtain from the application of the highest evolved ideas.

THE PRINCIPLES OF GOVERNMENT.

NO. III

It has been the intention to show the importance of unity of purpose in government, and that such unity of purpose can only be obtained by the application to administration of those principles which in operation produce unity in the kingdoms below the kingdom of ideas. Human government differs from all other kinds of government in this, that it is for the control of Mind instead of Matter. The natural direction the individual would pursue results not only from causes which arise in his material nature, but to these are superadded those which pertain to the Mental in contradistinction to Matter. Each individual is not only an epitome of all previous material forms which have been evolved, but he is also the finite representative of the Infinite Power which caused all those evolutions, and therefore has an individualized, determining power of his own to the extent that he represents the Infinite; and as this extent differs in degree so extensively among the total of individuals over whom government presides, it is the most difficult of all tasks to prescribe forms for it to operate through, by which it can reach and control this diversity.

This most serious difficulty which arises at every step in the search for the true source of government, comes from the innate sentiment of freedom in man, which is the truthful expression of the characteristics of the Infinite, which are indigenous, so to speak, to his nature. He involuntarily resists all attempts to exercise authority over him because of these sentiments. He feels, he realizes, that no individual, nor any number of individuals, has any authority from any competent authority to exercise supreme control over him; and thus it is that all individuals resist control.

Just at the point arrived at comes in the other part of the fact, which being considered, modifies the absoluteness of individuality. Every individual must either ever remember, or be compelled to remember, that he is but one of millions of individuals who live upon the face of the earth, each one of whom feels the same innate sentiment of self-right; and thus it comes that there should be no restraint at all over each individual exercising all his selfish ideas of rights strictly within his individual sphere; and that all these should be compelled to harmonize so that none may interfere with others. Even to this last proposition there are natural modifications to be inferred from everything below man. The higher order has the authority of its position in the natural scale of evolution, over all that precedes it; and this authority is of that absolute character which receives the sanction of nature in all the kingdoms which man can view.

The higher orders of ideas and thoughts should thus be the controlling power among men. They should assume the business of the artist in ideas, and prune, dig and destroy, if possible, all lower ideas which, live but to sap the vitality from the more advanced. The best expression, then, which it is possible for principles to find in the individualized productions of the highest animal form, must be sought in the most highly developed mentality; or in that mentality which expresses the most of the Infinite, and which is consequently the highest authority represented through humanity.

Mentality represents the most important department of the duality which constitutes the source of governmental power; but this, acting alone, would not prove the perfect principle. It would pursue its aims with no regard to sentiment or feeling. It would ruthlessly destroy all imperfections which debarred it from having absolute control, instead of endeavoring to consolidate their life with the higher and the better because it is the higher. To this active, sternly analytic principle, must be added the principle of unity or the affectional, which seeks to combine all mentality in one harmony. The head and the heart should act in concert; the head perceiving that the same general principles should be used to direct the forms of every department of life, and endeavoring to apply them to control humanity, should head the appeals of the heart, which, from its mainsprings of love and tenderness, feels, that the whole universe is bound together by the indissoluble ties of fraternity, and, therefore, should realize that as a father and mother, they should govern their children. Of these principles, government should be the true exponent, representative and administrator.

But here the question arises: How shall such government be inaugurated? How shall those who are the best representatives of advanced ideas and the broadest fraternal feeling become installed as the administrators of government? Every thinking person knows that no such persons or principles are in authority now, and that they have not been these many years. In the early days of the republic, which was constructed by men whose souls were imbued with these principles—or at least the fraternal principle—it may be fair to admit that something nearly assimilating to the true kind of government did exist. A government founded in the

principles ours was could not have been organized except by men of the very highest order of development in the true principles of government. They were hundreds of years in advance of the general people, for whom they wrought, and it may be seriously questioned whether they have had any representatives since, and whether they have any at present, who are actuated by any such lofty patriotism as they were. So long as they lived it was but natural that the people should have continued them at the head of what they had constructed, by the means they prepared for the expression of their right of self-government. It is well demonstrated that these men fully realized the principles of freedom, equality and justice, which realization comes from the conspicuous development of the paternal and affectional elements. Mentality, it is plain, was not so conspicuously developed, for they did not comprehend that the time would come in which those who should fill their places should be almost infinitely lower in the scale of true governmental principles than they were, or that the controlling motives of such could ever descend from their lofty stand to grovel in the purely selfish. But the time has come and now is, in the which the present places the fathers of the republic occupied are filled by those who are not in any sense the representatives of the true principles of government. It is quite true that the people are responsible for the men they select to represent them, but that does not better the very bad fact that the people are not represented, any more than that the true principles of government are. When this fact is seriously considered, it becomes apparent that there is a difficulty somewhere in the processes of government which has such imperfections that the ends of government as understood by its founders are utterly defeated. The result of this imperfection is, that instead of the true and best representative men of the country—those whom the previous analysis points out as possessed of the qualities demanded in government—being chosen to perform the function for which they are adapted, they are left one side, while others without ideas are sent where they should go. In short, the whole governmental operations have been and are being prostituted to the selfish ambitions of party leaders, who do not care a whit what means are used so that they win thereby. This shows not only that there are imperfections in the organization, but that there is much which is radically wrong. It is even now being more than whispered around that there is a plot being matured by which some of those who are now in power intend to continue themselves in power, even if they are obliged to seize upon the government in spite of the people. Such a plot could only bring destruction upon the actors; but that such a disgraceful thing could occur, or even be conceived, proves that a remedy is needed somewhere, which shall prevent such persons acquiring the power they would thus prostitute to their own purposes, at the expense of the sacrifice of the rights of the people.

This government is either a government for the people or for the office holders; latter practices incline outside observers to the opinion that it is the people's only in theory. If we examine the theory, it looks finely enough; but when the manner it is outwrought comes under observance, nothing can be found which entitles it to the name of the people's government. It is not the people's government by a very great deal; nor is it a government for one-half the people even; neither is it a government which guarantees equality to its citizens; every count which can be made is against it, as the exponent of principles upon which it professes to stand.

In the first instance, one-half of the people are debarred from all political rights whatever, and they are those who form the producing part of humanity, and whose interests in government are in every way equal to that of those who exercise all the political power. Thus at the very outset we find a professed equal government proscribing one-half the people over whom its authority is exercised; and, be it ever remembered, is fully maintained. While they are made responsible for all infringement of law, they have no voice in determining what that law shall be. While they are compelled to assist equally with the preferred class to maintain and support government by the payment of taxes, revenues, &c., they have no power to control the use that shall be made of them. This proscribed class, though living in the United States of America, a so-called Republic, are in no better condition and stand in no superior relation to the government they are compelled to give adhesion, respect and support to, than are those of the most absolute monarchy upon the face of the earth. What think you, enslaved people, of the great, the free, the exalted government of a country which professes so much and grants you nothing?

In the next instance, it is not the government of the one-half of the people it has really the semblance of being, and which many think it is. To completely establish this significant fact, the attention of the people is called to the immense minorities in the several States, and the relations which they sustain to a Presidential election, wherein the sum total of all the citizens of all the States who are permitted to cast their ballots, and who do so cast their ballots, for the electors who vote for the defeated candidate, exceed the sum total of all the citizens of all the States who are permitted to cast their ballots and who do so cast their ballots for the electors who vote for and elect their candidate. Such results have obtained; but a President thus elected is elected by the votes of the minority of the citizens of the United States who are permitted to vote, and consequently, within the Union as a whole, a person may occupy the Presidential chair against the will of the majority of the voting citizens of all the States. Such is the perfection of the forms which have been framed and used through which to obtain popular self-government; and such the results obtained.

The same line of argument applies with equal directness and force to the citizens of each State in relation to their entire State government, with the exception of such officers as are elected upon the ticket with the Governor; their representation in the lower House of Congress, and in their Legislatures and through their Legislators and their representation in the Senate of the United States may be, and often is, that of the minority of the voting citizens of the State. The same is also true of all incorporated cities outside of their general officers.

This condition of affairs shows that there are two conflicting principles ever operating against each other, and that their very worst features appear when their object is the “first office in the gift of the people,” which, above all others, should be filled by the choice of the majority of all the citizens of all the States.

Scarcely less in importance, as compared with the Chief Magistracy of the Union, is the importance of Congressional legislation, which should be determined by Representatives and Senators who should represent the majority of all the voting citizens of all the States. This government will always stand in danger of being overthrown by the unrepresented majority, so long as such forms of arriving at representation are allowed to determine these questions, which lie at the very basis of a republican form of government.

The whole difficulty which this question presents arises from the seeming stubbornness with which the people refuse to understand that the interests of the people as a whole can only be promoted by promoting the interests of each individual composing the whole. In this consideration the Democratic doctrine of States rights, to which the Democrats adhere even yet with so much apparent stubbornness, is utterly subversive of the first principles of unity and it may be emphatically stated that until enlightenment is obtained upon this point by the common ignorance of the country, there is no security from wars such as that from the effects of which we have not yet fully recovered. The same principle of States rights, as compared with those of all the States, if a correct principle of self-government, should also be recognized as the proper one to be acted upon in counties as against the State, and in cities as against counties and States, and in wards as against cities, and by citizens as against the wards in which they reside, and by the several partners of firms as against the authority of the firm as a whole. It is the only mischievous principle which is operating to destroy the Republic which is prophetic of so much civilization and advancement to the whole world.

Under the application of such principle a single government for all the “nations, kindred and tongues” of the earth would be utterly impossible and impracticable. Nothing but strife, contention and wars would follow a government founded on such principles of individuality as do not and will not recognize the superiority of the community as compared to the individual members of it. Upon this principle brought down to individuals, every individual would have the absolute right to act upon his own self-interests, no matter how seriously such action might interfere with others possessing the same right. The community would have no right to compel any restraints upon the individual under this principle of rule. This principle applied everywhere would carry us back to pre-historic times, when every individual was his own supreme authority, and maintained it at the risk of his life. This is the purest form of anarchy, and as such is laid down by all writers upon pre-historic times.

Why do not the advocates of States rights contend for the application of the same principle to its fullest extent, and thereby become consistent? Why do they advocate any general government at all? The truth and the facts of the case are, that such doctrines as recognize the rights of the individual as superior to the rights of the community in which he resides, are subversive of the first principles of order. Suppose such principles governed the entire sidereal and solar systems, what chance among so many vast planets would our little earth have? _It is saved from destruction because there is a Prime Power which compels them all into harmony of action and movement, whatever courses their individual proclivities would lead them to._ The application of this general superior controlling power in governmental affairs is the only method which can secure—because it will compel—harmony.

THE PRINCIPLES OF GOVERNMENT.

NO. IV.

Notwithstanding all this, which has been said in opposition to the doctrine of individual sovereignty as the true principle of government, it contains the germ of an ultimate truth, which will be realized when the total of individuals forming the world’s community shall have become so advanced from the present low conditions to those of wisdom and love, as to make every individual involuntarily recognize the rights of every other individual. In other words, individual sovereignty will be the principle of government when that time shall come wherein there will be no necessity for government, because the people shall have grown into the condition of a universal brotherhood. It is this innate sense of individual right which is present in the consciousness of every individual who has grown to know he is an individual, which makes this constant conflict between ultimation and approximation. It is

the expression, politically, of the same principle which, religiously expressed, makes it possible for the consciousness of the individual to contain an undefinable knowledge of a Great First Cause, and at the same time to feel that he is an individual agent. In other words, it is the old doctrine of free agency reproduced in the political world, which, if it is but considered a single moment with an unprejudiced mind, it must be seen that there is no such thing as free agency; for every individual is dependent upon something, over which he has no control, every instant of his whole life, which something even produces the capacity which gives him the power to think he is free.

It will be seen, then, that the great general principles which govern the entire universe, are recognized in the proposition that all people are born free and equal, and entitled to life, liberty and the pursuit of happiness, which are inalienable rights; but it fails to be comprehended that the inalienable rights of freedom are limited by the other condition of equality, which makes every individual free within the distinct sphere of his individuality, but not free within the sphere of other individuals. He has the inalienable right to life, liberty and the pursuit of happiness, when it is not exercised at the expense of the inalienable rights of others in the same direction. These are the governing laws which the worlds obey, and which control the minutest particles of matter. And these are the true “Principles of Government.”

It will be also seen that the forms by which the principles of our government are administered are imperfect, and consequently that, however much we may reverence the Constitution of the United States, it requires remodeling to enable the true principles of government to find expression through it. The inconsistencies, also, of the rights of States, as represented by the common government, must also be removed. The State is either the source of governmental power or it must proceed from all the States, as combined in government. If the former, we are no more to be respected as a Union than the numerous Italian and German States were before the consolidation. The republic, under such construction, amounts to nothing more or less than a union for offensive and defensive purposes, _at the option_ of the several States, which is as purely a governmental force as could well be imagined. The inconsistency of this construction of the Constitution was fully shown in No. III. of the “Limits and Sphere of Government,” and need not be repeated here; the subject has been pursued here, that the utter folly, inconsistency and impossibility of the recognition of individual rights, where such rights conflict with the community as a whole, might be the more palpably apparent. Having considered the source of the imperfections which exist in the form of our government, what should legitimately follow for consideration is, the remedy. In the first place, the theory of States rights must be abandoned, and each State must become a member of the Union by organizing under a common form, to be prescribed by them all, or by the present required constitutional majority of them all, to make an amendment to the Constitution valid. The same rule should be applied as that which has come to be a recognized necessity in States regarding incorporating companies. All the States should be required to organize under a general State law, which should be clearly and concisely set forth in the Constitution, which should recognize the general government as the determining power, and not that it exists by the sufferance of the States, but that the States exist as organic bodies, because they have complied with the requirements of the Constitution, which was necessary to constitute them States. In conformity with such acquired power, States should prescribe the means by which cities can become incorporated. In this way, unity of purpose and harmony of interest can be secured from the individual up to the total of individuals forming the nation.

Such a government would be a strong government indeed, but one in which its composing members of States and the composing members of individuals would have the utmost extent of freedom that the interests of the whole would admit. If this is not the end to be gained by government, then government is a simple farce, and unworthy of being allowed to exist anywhere. From the earliest historic ages the world has constantly been extending to individuals through its forms of government, more and wider freedom and greater privileges and immunities. This process will continue to spread, as the general people become more and better fitted to be the recipients and the appreciators of such extensions to them.

The individual has more rights and privileges to-day in the world than at any other previous time, but all individuals have not yet become such perfect laws to themselves that no formulated law is required to restrain them from the infraction of others’ present rights, privileges and immunities. Until such time come, a strong central government is required.

A strong central government does not necessarily mean anything approaching a monarchy. But it does mean a republic which will have the support of all its citizens as a central support, instead of each State comprising the Union reserving to itself the right to differ from the central power. In such a government, the majority of the people would, at any time, have the right to elect new officers, as provided for, so that the strong central power would not be in the individuals administering the government, but in the organic law which constitutes the several parts of the country a common government, which, while being the strongest possible governmental form, it would, at the same time guarantee the greatest possible freedom, equality and justice to its people which would be compatible with the common interests and the common good.

Lastly, such a central power of government is the only one to which peoples not already within the government could be admitted without endangering its existence. A new State desires to become associated with the several States forming the present Union. Immediately she is admitted, she has, under the present doctrine and practice, the right to withdraw. She has been admitted by and with the consent of the required majority of the States previously constituting the Union; therefore, logically, she has not the right to withdraw without the same consent It required this consent added to her free and self-expressed desire to become a State; it should also require the same consent before she should be allowed to withdraw from the Union.

Under a general rule for the admission of new States, and of allowing addition to the present limits of the Union, all that would be required would be for the people of a certain limit to adopt the requirements of the Constitution, and present themselves to Congress for admission. Aggregation, according to this rule, could always proceed without ever endangering the safety of the general government, because a country once having become a part of the Union would be under the mighty constraint of the whole Union to properly and peacefully perform the functions of a State in the Union. This condition can be well illustrated, by supposing that there was a confederation of all the European powers to preserve peace among themselves under certain defined agreements. If a single power violated any of those agreements, or attempted to make war upon its own account against another nation, a party to the agreement, all the other contracting powers would be in honor bound to make the interest of the nation against which proceedings were being had contrary to the common agreement their own. War, under such conditions, would be practically impossible. So would disunion, under the proposed system of confederation.

The country which shall first adopt such a system will be the centre of the future Universal Government of the world; and it is with this view in mind that these suggestions are offered to the people of the United States of America, which country is, by the common order of the universe, appointed to be that centre, to the end that they shall see the necessity of immediate action to perfect the organic laws of the country.

PAPERS ON LABOR AND CAPITAL

NO. I.

It is a mistaken notion that the interests of labor and capital are in any way antagonistic to each other. This fallacy has, however, taken such hold of the minds of the representatives of both these interests, that it is engendering a spirit of bitterness which, it is to be feared, will grow into as fierce a character as that against slavery did. It is always hard to produce any argument that will convince this spirit If convinced, the spirit of opposition will not be calmed, and obstinacy, assuming the place of all sentiment, compels the individual to remain rebellious.

It is most true that there could be no capital unless labor first existed. This stamps labor as of the greater importance. Let a person be cast upon a fertile island, without pecuniary means, and he will live by labor from its fertility; but let him fall upon an utterly barren and sterile land, and all the millions of a Rothschild would not insure his existence. So it is everywhere, and under all circumstances, to a greater or less extent. Labor can exist—though not flourish—without capital; but capital cannot exist entirely divorced from labor. Being dependent upon it for primary existence, it must ever remain under a direct analysis in the state of semi-importance.

The capitalist is the more unreasonable of the two in the position he assumes. He continues to apply all his energies to the acquisition of wealth, utterly regardless, in most cases, of any idea of justice to what has given it to him. The general practice is—and this is the true test, for whatever is of general application must be governed by some underlying principle of right—when capital requires any given thing done which it is obliged to apply to labor to accomplish, it must give one-half interest in the venture to enlist its co-operation. This is true regarding nearly all speculative pursuits, and when there is an actual necessity for either to apply to the other for aid to carry out its desires, this rule of agreement always obtains. This forms one of the most conclusive arguments by which to demonstrate the true relations of labor and capital, and should be made the basis of all co-operation.

It is not for the best interests of the wealthy to become still more so at the expense of poverty to those under them. On the contrary, it is their true interest to render fullest justice and strictest equality to the demands of labor, to be determined by the principles that shall promote the most general good. It is the greatest mistake of the age—it has been the greatest mistake of all ages—to suppose that individual benefit must accrue from the acquisition of wealth at the expense or sacrifice of any general principle of justice. It is also a great mistake for labor to array itself in opposition to wealth, and to form combinations to control it. It is too late in the ages for these kinds of arguments to convince. They can only end in producing still more injustice and distance between the

two interests, which distance will be filled by rankling bitterness and contemptuous insinuation. An approach of the two interests is what is desired—an assimilation of them, so that the same end shall be best for each.

It may be laid down as an unanswerable proposition that there can be no general happiness, peace or comfort among a people so long as the principles society is built upon tend to promote unequal distributions of the products of labor; and this brings us to the consideration of the remedy. It is to reconstruct society upon such principles as shall tend to promote complete unity, harmony and equality among its various classes. To accomplish this it should be the special aim of every one possessed of wisdom enough to comprehend a common logical proposition to endeavor to bring about this equality by diffusing the deductions of it, in all possible ways, among both classes. Let the various producing and exchanging classes exist as they do, but let their relations be governed by such rule of law as shall render them equal, both as to caste and to the benefits to be derived from an equal interest in the common cause of the brotherhood of mankind.

NEW YORK. July 10, 1870.

PAPERS ON LABOR AND CAPITAL.

NO. II.

The strife that is being urged to create divergence between the interests of these bases of society is purely the result of ignorance of the first principles of constructive use on the part of their representatives. Instead of an endeavor to demonstrate to the understanding of all, the true principles which underlie these interests, which would effectually unite them, those who have selfish personal ends in view seek to further them, by engendering a spirit of bitterness and a desire for strife. There are those who cherish the ideas of aristocracy who have no wealth, on the one hand, and are too indolent to endeavor to attain their desires by active labor, on the other, who think to create some serious diversion, and upon it to ride into place and power. This class of individuals are ever busy stirring the coals of dissatisfaction into flames of rebellion, thinking thereby to become the acknowledged representatives of the labor interest. It is generally true that a cause supported by such means has no principles upon which to base its claims; but in this instance the most absolute and just principles are ignored, while cant and bombast usurp their proper sphere.

It is quite true that there is a growing tendency to centralize capital, and that consolidation of monetary interests is the rule; but the fault of this does not lie in capital or capitalists—it is farther back than it or they. It is in the people themselves, and in the fundamental principles upon which society is built, and those which the people allow government to be administered upon. If the laws of a country permit the doing of a certain thing, which it is for the interests of a certain few to do, and they chose to avail themselves of it, there are many to be found in these times so much governed by the desire for the public welfare as to take the advantage offered them by the people, for it comes down to that at last. The labor class have it in their power to send to Congress just those who shall fully represent their interests; but they do not do this; most of them are found actively supporting those whom Capital selects and holds up for their suffrages. The remedy lies with the people, and they must make use of it before they can ever expect to see their rights adjusted.

There is, as was said above, no conflict between Capital and Labor. The conflict is among their representatives. On the contrary, there is an entire harmony of interests between them. The true interests of each are best promoted by rendering justice, full and complete, to the other, and in the understanding of this lies the _only_ solution of the Labor Question. Strife may continue, war, even, may come of the strife, but finally the settlement must be made upon the principles of justice, which underlie their relations. One comes from the existence of the other; this, when created, should ever acknowledge its paternity, and never assert supremacy, nor be allowed to do so; to be so allowed shows that defects exist in the fundamental principles of government, or in its application to existing things. These defects it should be the duty of those who prate with so much volubility to discover and proclaim, to the end that they may be understood by the people. The people in turn should send as their representatives to frame laws, such persons as shall make it their business to attend to their duties rather than those who allow themselves to become immersed in the schemes of plotting politicians who seek eternally to continue themselves in place and power, and who lose all sight of, or care for, their constituency, in their necessarily continuous efforts to secure that end. Such representatives should be religiously ostracized by the common people, and none tolerated but such as understand the relations which the interests they wish fostered bear to those they feel they are becoming subjected to, and who will unflinchingly advocate them at all proper times and in all proper places. The durability of government rests upon the entire harmony of all the interests it is framed to protect, and no country can ever become continuously prosperous that has within it the elements of discord; no country can endure for any length

of time that does not seek to eradicate all causes of dissatisfaction, and to so adjust its interdependencies that they shall be mutual and just to each as individuals, and to all as the public.

NEW YORK, July 20, 1870.

PAPERS ON LABOR AND CAPITAL.

NO. III.

The duty of the philanthropist is to point out the harmony of interests that exists between the extremes of the different grades that society consists of. There are a certain class of would-be reformers, who make it their business to stir up strife and contention between these grades, and thus to separate their interests, and to make it appear that they are antagonistic. The number of the latter class as compared with the former, gives them a preponderant influence, which, added to the real grievances existing, enables them to create considerable excitement and much imagined wrong, which has no foundation in fact.

The laboring classes, being occupied by their labor, do not devote much time to the study of the circumstances that control their condition. They see that other classes fatten from their productions, and without stopping to inquire why it is so, straightway conclude that they are the subjects of an oppressive power which desires to completely wrest the results of their labor from them, and to always keep them in the condition of virtual vassalage. This conclusion rouses the spirit of independence in the laborer, and he determines to redress his wrongs. He sets about forming combinations, having in view the control of wages and hours, not comprehending that the remedy lies deeper than these, or that these would regulate themselves, could the true cause of the condition they rebel against be reached and generally understood. While it is true that capital can never enslave labor to a degree that can be considered compulsory on the part of capital, and unnecessary on the part of labor, it is equally true that labor cannot compel capital to its commands. Therefore both these methods of cure should be abandoned, and preventive means be resorted to instead. And these it is our duty to point out.

The judicious architect, before pulling down the old structure, provides the material to replace it; in other words, he substitutes the new for the old, and in the process leaves no unnecessary interval in which the fostered interests shall be left to the vicissitudes of anarchy. It is evident from the rapidly spreading knowledge among the laboring classes, that they will soon demand some modifications in the forms, and in the relations they sustain through them to society. Before breaking down the present organizations society exists in, by revolution, which would end in a period of anarchy, out of which better conditions _might_ grow, the better conditions should be first considered, prepared and determined upon, and, by being thoroughly understood, should be substituted for the present by general consent, without society being compelled to pass through the anarchical period that succeeds all violent disruptions of present forms, whether in government, religion or society.

As society is constructed at present, it must look to legislation to produce forms and to enforce order through them, that society may observe in their operations the better results to them. Society expresses itself most powerfully through legislation. Public opinion is a force capable of many things, but is powerless to redress grievances or to institute the new and better for the old and decayed, unless it is directed by the formula of law. All the energies of labor reform, then, should be directed to the main point, from which benefit to itself must spring. It should waste no time nor strength upon the minor issues, but concentrate all upon the one strategic point. And when this concentration is effected, it should not fritter away its strength by dealing with the contingencies of the present, or in small expedients, to enable us to dodge along, simply escaping shipwreck, to be again forced the next day, week or year, to the same expedients to escape similar shoals. Instead, it should direct all its capacities to substitute a new and better foundation, upon which a new and better superstructure of society can be reared. How shall such a work be begun?

Legislation is the primary constructive point from which better conditions must emanate. The laboring classes, then, must see to it that they are properly represented in legislation. Nor should they be deceived into the support of any who, by bluster and tongue, loudly proclaim themselves the champions of labor, without the understanding of the first principles that control the relations of labor to capital. Let it be set down, once for all time, that he who denounces capital as the oppressor is not the representative labor should choose to right its wrongs. In every community there are some who think a great deal and say little; these, as a general thing, are the antipodes of those who say a great deal and think little. Though the last are usually found floating about the surface of society, it is to the first, society must look for that wisdom, judgment and executive ability that shall guide it to the desired harbor.

It should be the first duty of the labor interest, in each State or national district, to select and elect one from that class that has calmly observed the workings of present systems, and who can show where the cause of existing ills lies. It is to the philosopher,

and not to the politician, that the labor interest must turn its eyes, and though he be not smooth of tongue and glib of speech, he will lay such a foundation in law as will produce the conditions desired. Your present representatives, State and national, have shown themselves incompetent to the task you demand of them. Leave them to seek their level, and turn you to others, who will not lose sight of your interests in the allurements which place and power present. You cannot expect that those who are not of you can appreciate your wants or understand your conditions. Choose from among yourselves and you will not go far astray. There are, however, noble exceptions to this rule of decision. There are those who were reared in wealth whose hearts sympathize with you, and who feel quite as keenly as you do the injustice you suffer. In these you will find your best advocates, but see to it that your suffrages are never, once again, worse than withheld.

You are in the majority, and the fault is your own if you do not make use of the power you possess. Nominate and elect your own men; if your first choice fails you, try again, and continue trying, until the right man for the position is found; and when found, while holding him strictly accountable, give him your cordial support while he is true to your interests. Most persons who occupy position now, feel compelled to yield principle to the demands of policy, in order to retain it. This must be remedied. None are fit to hold position who will sacrifice one iota of their conviction in order to retain it. Self-interest must be surrendered to those whose power fills the place, and for the time being it must act as the representative of them and not as its own. It cannot be too strongly insisted upon, nor too often repeated, that it is the first duty of the labor interest to look to it that our halls of legislation are filled by those who understand the true and the harmonious relations of labor and capital.

NEW YORK, July 27, 1870.

PAPERS ON LABOR AND CAPITAL.

NO. IV.

In our last the attempt was made to show how important the laborer should consider the choice of representatives to be, and also what class of persons should be chosen. The task of making these selections cannot be begun too soon. In every district in the Union the laborers should be made alive to this question. Some who fully appreciate its importance should take it upon themselves to begin the work; they should converse with the few they come in contact with, and these, becoming interested, should be induced to extend the agitation; and finally, all over the country, primary labor meetings would come to be held for the full and complete discussion of the whole subject.

It is the most complete evidence of supineness on the part of the laboring classes that they are not now represented as they should be. Being so vastly in the majority, every office should be filled by them. The difficulty has been—and we fear will be—that while the laborer has been busy at his regular task, others have managed the incipient stages that produce the candidates, in such a manner that the interests of the majority have been entirely ignored. Finally, when the regular party ticket is presented, the least objectionable one receives the support; and thus it comes that the real interests and wishes of the people are seldom represented, and as seldom is the elected candidate the real choice of the people.

Unless our laboring classes arouse themselves to the real importance of this matter, and become willing to devote sufficient time to preparing their candidates, they should cease blaming others for results; for they now complain of things they have it in their power to remedy, but which they cannot expect others, whose interests seem to be at variance with theirs, to correct for them. Those who declaim so loudly and profusely about the wrongs labor suffers at the instance of capital, should be strictly guarded against, lest they, unwittingly, become your leaders and advisers.

There are at all times numbers of persons standing waiting and ready to step forward to take advantage of any favorable movement among the people which seems to offer inducements. It matters not to them in what, or where the movement may originate; they have no principles to crush out or control in order that they may fall into the current. It is almost impossible to escape the curse of these ever-ready tools. The safest and surest remedy against them is to select those who have never mingled in politics, and who will come direct from the shop or the field. It does not matter so much if they are not able advocates, if they only understand the work to be done and are devoted and true. Let this course be pursued a few years, and the enormous proportion of lawyer-legislators would be diminished by one-half. Many of these have no sympathies in common with you, most of them are, by all their controlling influences, drawn from the consideration even of your condition. What does it matter to them if the few articles you must purchase to render yourselves and families comfortable, cost you ten, twenty or fifty per cent. more than the actual cost of their production, if corporations for which they are attorneys become still more corpulent upon this that is indirectly filched from you!

For, do you not know that capital under such rule does not pay the taxes of the country, but that your labor does? In this way, the common laborer, who should not be compelled to pay any levy at all, is taxed on almost everything he eats, drinks and wears, and thus labor is compelled not only to produce what makes wealth possible, but also to sustain it after having produced it. This is a vast inequality in favor of capital and against labor, and still it is the laborer's fault; and it lies just where we pointed, in the selection of proper candidates as representatives, State and national.

There are but a very few newspapers that do not _profess_ to be the advocates of the rights of labor. Let them be called upon to take hold of this matter, and take hold of it at just that point where the remedy must be applied. Let them lay before the people a plain exposition of the matter, and certainly aim to make the people understand it. Let them urge the people to assemble and concert plans and devise means to carry them out, and to warn them to no longer intrust the most vital parts of the "necessary course" to the care of hereditary members of the caucus, whom money buys or whisky controls. It has become proverbial that he who would be elected to any important position must dispense both these "powers" with a lavish hand; and he who can do this the most profusely is pretty sure to "be elected." You may rest perfectly assured that if he spend ten thousand dollars to secure his election by your votes, he intends at least to double his venture during his official term. You should know by this time that "the purity of the ballot box" is simply a "play upon words," and that elections are but farces to approve what is previously determined.

The people, then, must look on every side for treachery to their interests and dishonesty of purpose, not forgetting that a large portion of the press that profess your interests so warmly, that you almost know their truth, are open to the influence of at least one of the abovementioned powers, and that to go counter to the _commands_ of those who "back them" is to go to certain destruction. Nevertheless, demand of the press a course that cannot be denominated hypocritical, and if it does not respond, withdraw your patronage, and give it where it will contribute to your interests.

These introductory details cannot be dwelt upon too long nor insisted upon too earnestly. To begin a work right, is to have it half accomplished; and most powerfully does this apply in the matter of determining who shall be your representatives.

PAPERS ON LABOR AND CAPITAL.

NO. V.

One of the great questions of the day, if not the greatest, is the true relations that should exist between labor and capital. It is one fraught with more direct benefit to a greater number of people than any other question has even the external appearance of being. The real merits of the question are of much greater significance than is generally supposed, even by those who raise it. The welfare and the individual rights of three-fourths of the people are at stake. The question assumes this shape: Labor has, by its continuous efforts, produced a certain amount of wealth, from the use of the materials nature presents, that has not been required to support and sustain the general life of man. By certain advantages, either of general policy or of individual acuteness, certain individuals have accumulated more than their necessities demanded they should expend, and this accumulation has become an added power to that possessed by the individual previously, which power endeavors to maintain itself partly at the expense of that which first produced it, and to transfer just so much of the cost of its production from itself.

That such conditions can exist and really increase in power and importance, so that they can virtually control legislation, gives evidence that principles are operative that do not promote the interests of the entire people. There must be a fault somewhere, which fault it is necessary to discover and expose, and then remedy. Now, where does this fault really have beginning? It is in certain protections and guarantees that law extends to individuals, which permit them to have an advantage over those with whom they sustain the relations of society. These laws arise out of false conceptions of the principles of common equality and economy, which pertain to man as a common fraternity. In legislation, which first allows and then fosters such departures, then, must the point at which reform should begin be sought. Any attempt to teach the general mind can have no practical effect, unless, finally, the result of the teachings express themselves through legislation. Legislation presupposes legislators, and to have the right kind of legislators involves the necessity of the laboring classes giving sufficient time and attention to the matter of nominations and elections to insure that those who will represent their true interests shall be returned.

Although the remedy for all the laborer's ills must be sought through legislation, there are, nevertheless, many fallacies still received, even by the laborer, that have the direct tendency to degrade labor and to elevate the position of capital. One of the principal of these is a false monetary basis, a false representative standard of values, which is arbitrarily imposed upon the people, with no positive and absolute value within itself, except that which such arbitrary law gives it. Gold, as a standard of values, has

been set up and worshiped so long, that people submit to its decrees with about the same appreciation of its real merits that they have of the mysteries of religion, as expounded by their paid oracles, who have constituted themselves into authorities to declare, “Thus saith the Lord.” The people have surrendered their reason in these matters to these self-constituted authorities, and so have they surrendered common sense to the god of value.

Another, and almost as important fallacy, is that of interfering with the natural ebb and flow of the products of the world by imposing upon certain of them such tribute as makes it pretty nearly impracticable for them to find their way to the locality of natural demand, in order that a special few who inhabit that locality may produce the same at a greatly increased cost, which the consumer must pay in order to obtain. It does not matter how this plain statement may be twisted and bent by the alluring sophistries and glittering generalities of the protectionist; a plain statement, viewed with clear light, needs no authoritative sanction to determine its truth. If it be any benefit for a thousand men to pay one man ten per cent more for a desired article, because it is of home production, than it could be purchased for from a foreign producer, we should be most happy to have it demonstrated. The argument used is, that by that one man being protected in its production he is thereby enabled to give employment to a certain number of laborers. But to make even this tenable upon their own statement, they must at the same time prove that those laborers would not have been able to apply themselves to any other labor during the time required to produce the article in question. This at once leads to such an intricacy of cause and effect that those who attempt to solve the mysticism prefer to accept the declaration that protection is a good thing rather than acknowledge that they are lost in the fog and obscurity they have been sent to explore to find the required evidence.

Another extensive popular fallacy is that of the continuation of special protection to monopolies after their existence as monopolies is assured, which renders them perpetual taxes upon the labor that must make use of them, and perpetual patents upon the industry of the country, by which a few already plethoric capitalists become still more obese. The great systems of internal improvements of the country belong to the country, and the country should so arrange their conduct that the people could make use of them at the least possible expense of support.

It is these and sundry like matters that the laborers of the country should require their representatives to understand and act upon, and they should cast their vote for no one that will not, at all times and under all circumstances, advocate and vote for the greatest good of the greatest number. In this way, labor may hope to arise from its present position of degradation to sit side by side with capital in all public and profitable positions and those of honor and trust.

NEW YORK, August 10, 1870.

PAPERS ON LABOR AND CAPITAL.

NO. VI.

From various sources we learn that there is beginning to be a manifest interest in all the different States and Congressional districts regarding the next elections. The representatives of labor seem to begin to realize the great importance of special attention to all that belongs to primary organization, and to perceive that heretofore they have been obliged to throw their strength away or waste it in unprofitable directions, from the very fact that they did not give the necessary attention to the first steps in the process of determining who should be set up for them to choose between. It does not seem possible that any should be returned to office who entertain opinions antagonistic to the general interests of labor. Three-fourths of the entire population of the country are in this interest, and whether they be artisans in mechanics or nature—whether they be by the anvil or the plow—whether they be printers or writers—their interests are all the same; it only requires that they should all understand this to consolidate them into a power that would control every movement of government. Should this unity once be found practical, and should it be recognized by capital as consummated, its representatives would be compelled to come to those, who now look to them, for the granting of ameliorating conditions. It is most probable that when such a unity shall be attained both the capitalist and the laborer will, for the first time, discover that whatever really militates against the true interests of one, is equally antagonistic to the best interests of the other.

Some who have thought this might be so, have endeavored to devise methods by which harmonious action could be secured. Various schemes of co-operation have been suggested, many of them tried and found faulty and then discarded, until it has come to be pretty thoroughly understood that there is no level upon which they can meet and part in mutuality of interest. It is true that no perfect method can be suggested or instituted that will from the first give complete results; but the principle must be sought that governs the relations between the separate interests and applied, at first, with imperfect results, which must afterward be improved

as the interests grow into a true comprehension of each other's character.

The principle is this, that labor and capital are equally interested in the productions that flow from their joint operations; that is, the capital that gives employment to one hundred laborers is entitled to an equal interest with the laborers in what is produced. But here is an inequality to begin with. The capital may only represent one individual, while the laborers are one hundred; still, this is the relation, and the final result of its operation will be a complete equality in this wise: The one hundred laborers perform their regular duties, receiving therefor such regular wages as are proper; and also their respective proportions of the profits of their productions. In, say, five years, these one hundred laborers will have accumulated a sufficient capital with which to transact the business on their own account; and here is where a system of equality is reached, which again would be followed by another degree of progress for the laborer. The capitalist, finding himself left out of the count by the operation of this method, would come forward and offer his capital to labor organizations at a reasonable rate of interest, and in this way a common interest would be the only possible result. The entire profits of the labor would then be divided among the producers, while the capitalist would have to be satisfied with the moderate interest he would realize, in place of the extraordinary sums now sometimes acquired from the sweat and muscle of the laborer. There is one point, however, in the first instance, that modifies the inequality mentioned in a very material degree. The capitalist, while enjoying as much profit as all the laborers, is also liable for all losses, in which the laborer has no interest.

Following the results of the co-operation above mentioned would be various modifications in society and in the locality of populations. People engaged in the same pursuits would naturally gravitate to each other and into distinct localities, while the various interests they represented would gravitate to those localities that should offer the most inducement to their respective trades. One of the results of this would be that all raw material would, in all cases—where all the requirements were present—be manufactured in the locality of its production, thereby saving vast amounts of transportation; and this again would be illustrative of another department of general economy, in the light of which protection to special manufacturing interests would be seen in its true colors.

We have thus briefly endeavored to point out the practical results that would flow from the adoption, generally, of the true principle of co-operation for the specific purpose of assisting the labor interest in selecting candidates for their representatives, both State and national. They should be those who understand these relations, and what would naturally follow them, and who would at all times, and under all circumstances, advocate their adoption, and, in the first instance, such policies as would most materially assist in their development, and lead to their introduction and practice on the part of all who compose both interests. Labor is the basis upon which all society rests, and nothing is entitled to so much consideration at the hands of legislation. Nothing heretofore has been so grossly neglected, insulted and imposed upon.

NEW YORK, August 20, 1870

PAPERS ON LABOR AND CAPITAL.

NO. VII. PRIORITY OF RIGHT—THEIR POSITION IN THE PROCESSES OF SOCIETY—THE EARTH BELONGS TO MAN AT LARGE—INDIVIDUAL CLAIMS, PURE ASSUMPTION—PRINCIPLES, PRACTICE, REMEDIES AND CURE.

Capital, primarily, is the product of labor, but labor, in the abstract, could produce nothing of itself. It must have something upon which to apply itself. It cannot create anything; it can only alter, readjust or rearrange the materials which nature offers, and by bringing them into new relations with each other make it possible for them to subserve other and better purposes than when, in the constitution assigned them by the operation of natural laws, they are unmodified by the touch of mind. Therefore, while capital is the direct result of labor, labor would not be possible without the free gifts of nature. Absolute originality, then, or absolute priority of right, as between labor and capital, cannot be claimed by or for either.

The formula of the operation, beginning with nature and ending in the ultimate use of its productions, in contributing to the happiness of the race, is this: Nature is made up of the elements of the universe, which, compounded into forms, are offered to man to be modified into other forms and to combine in new relations which may best contribute to the needs of the human family. In this view, and in view of the inharmonious relations that exist between capital and its co-equal labor, it becomes necessary to give the whole matter a complete analysis, in order to discover, if possible, where the primary fault lies, and to find the proper solution of all differences.

The human race exists upon the earth. At a past period no human being existed upon it. At a later day the human race arose. Before man, nothing claimed the ownership of any part of the earth's surface. When man presented himself he began to make use

of various parts of it for his own ends, but to the land thus appropriated he acquired no permanent title or right of ownership. It was his to obtain from it all that his genius and strength made possible. So much as he could thus extract he could possess, but further than this his title was valueless.

The races of men that now inhabit the earth are scattered over the greater part of its surface, drawing what it spontaneously yields and what they can force it to yield. From these premises it would seem unquestionable that each individual of the human family had an equal right to its benefits. The only difference that ought to exist should be that limited and bounded by the capacity of each to produce. No person could therefore ever acquire, under the rule of universal justice, an absolute ownership to any part or portion of the earth's surface. If the chain of title to any claimed ownership is followed backward sufficiently, it will be found to have originated in an assumption in the first instance of ownership to something that belonged to men in common.

We can now acquire landed property from the government, and this creates the most absolute ownership that can exist; but here again comes the question whether governments can do what is impossible to individuals? Can a system organized by a people perform acts not in the power of the people themselves to perform? Can a government by the mere fact of having been organized to preserve harmony among a people acquire an absolute title to the earth that is contained within its jurisdiction? If an individual cannot go into an unclaimed territory and take absolute possession of a certain portion of it, then no number of persons, nor can any government they may establish, do so. And here exists one cause of discord between labor which produces and capital which monopolizes.

All monopolies arise from landed monopolies. Were there no inequalities between men in claims to certain areas of the earth's surface, no other monopolies would find a basis for existence. Every individual should have a right to the use of a certain quantity of the real estate of the country, and the right to all improvements he might make upon it. Here would be a basis of equity which would forever prevent the accumulation in the hands of any few persons, of vast quantities of real estate, which is the real basis of all securities. It is such a basis because everything is produced from it. All manufacturers must rely upon it for their raw material, and, therefore, a practical equality in the occupation and use of the public domain would insure a certain degree of equality in all things that might spring from it. It was the perception of this principle that caused Lycurgus to divide the lands of Lacedemon equally among all the people; and a general recognition of it should now take place.

While these are the principles that underlie the workings of society, and which must be practiced before a general equality can exist, it is not to be expected that they can be immediately introduced. There are too few who understand the real rights of man, and too many who do not wish to understand them. While this condition of ignorance and perverseness keeps the world inharmonious and subjected to suffering, we should avail ourselves of all the alleviatory methods that can be suggested in our present system. Between two evils choose the least; but in the pursuit of remedies, the root of the disease should never be lost sight of. Nor should the spirit that is exhibited in many so-called Labor and Workingmen's Journals be encouraged. Strife and animosity will never accomplish half so much as calmness, reason and persuasion. "Come, let us reason together," was never more judiciously proposed than it could now be by capitalists and workingmen. The latter must remember that they cannot compel capitalists to their terms, and capitalists must not forget that if there are real causes of dissatisfaction growing out of injustice, the sooner justice is done the less serious will be the reckoning with the laborer. Instead of strife let us have co-operation; instead of war let us have peace; instead of the process of fermentation let us have that of mutual understanding.

NEW YORK, August 27, 1870.

PAPERS ON LABOR AND CAPITAL.

NO. VIII. THE CINCINNATI CONVENTION—NEW PARTIES AND NEW ISSUES—PEOPLE'S EYES OPEN—DETERMINATION TO TAKE MATTERS INTO THEIR OWN HANDS—WILL THEY MAKE JUDICIOUS MOVEMENTS?—THE RIGHTS OF LABOR—SHALL THEY BE IGNORED?—OUR POSITION REGARDING THE LABOR MOVEMENT.

The National Labor Convention lately held in Cincinnati was called for the special purpose of beginning an organization having in view the next Presidential canvass. It had taken the means of obtaining the views of a number of the most prominent public men, letters enunciating which views were duly presented before the convention. That of Governor Geary, of Pennsylvania, appears to have occupied the position of most prominency, and to have been regarded with peculiar and unanimous favor. The views presented by him are such as were sure to find favor with the representatives of labor, and so far he stands A No. 1 as the prospective candidate for the Presidency of the National Labor party.

It has been very evident for the last year that the old parties had lost their power of inspiration over the people. The Democratic party sold itself out to slavery and virtually died when slavery died. A party may exist called Democratic, but it will be upon new issues and must take new departures. The hard conservatism that attaches to it from its former practices does not suit the spirit of the eighth decade of the nineteenth century. The rank and file that have so long blindly followed wherever their leaders commanded are becoming imbued with this spirit, and they begin to realize that they have been mere automatons that have been moved with no acquiescent will of their own. Newspapers have become too commonly read. That the blind should be led necessitates the continuous condition of blindness. So, too, with, the understanding. What have the masses known of the essence of the issues that have formed the platform of the political parties for the last fifty years? When war came, as the result of a blind course on the part of politicians, the masses began to open their eyes to the fact that they had been unwittingly betrayed into a most dangerous and fearful condition, wherein it became necessary to cut each other's throats. Since the close of the war they have not only kept their eyes open to the full extent the war opened them, but they have also opened their understanding and for the first time fully realize that they are indeed freemen; and to become conscious that heretofore they have been so only in name. Awaking as they have from the delusion so long hugged to their hearts, it will not be strange if they do some inconsiderate and short-sighted things.

It is the duty of all who have the true interest of the whole people at heart to warn them of all the extremes they are likely to contend for, and to suggest permanent practical methods, which shall spring from principles that will apply at all times to all men—and women. The Republican party being composed of somewhat different elements is disintegrated from different action of the same causes; with the destruction of slavery and the reconstruction of the country its strength was expended. All people who were opposed to slavery had concentrated in the Republican party, because of the similarity of sentiment upon this single question; this settled, they find themselves without a common rallying idea; they differ as widely upon the old and common topics among themselves as they differ from those who do not belong to the party and never did. Place and power are the sole things that hold the Republican party together at all; these gone it will be gone.

It is just at this time that new parties are demanded, and they are sure to arise. The conditions are all favorable. It remains for wise counsels to prevail in the formation and departure of these, to insure them something more than death with the accomplishment of one of their central ideas, which destiny fell to the lot of the Republican party. Unquestionably there will be a Labor party in the next canvass. We are sorry it is denominated the Labor party, because it should be something more than a Labor party, and because this is a direct challenge to capital, and it will very probably result in arraying these two interests in an antagonism which will be but a repetition of the slavery antagonism. No party built upon a specific idea, looking in a single direction, can ever attain to even the promise of permanency; and it is for this reason we say we are sorry to see a party sectionalizing itself at the very outset of its attempting a general movement toward organization.

It seems, also, a little premature that an organization calling itself a Labor organization, should at the outset put itself upon the record against the freedom of labor, let it come from whence it may, and be of whatever nature it may. This policy is short-sighted, and will prove a stumbling-block to the party, though for the time Chinese emigration may serve for a rallying-cry. All assertions that the Chinese emigrants can be reduced to a system of slavery among us are humbuggery of the first water. There is no law to prevent a person contracting with a hundred American workmen at the best terms he can. It is quite certain there is no law to prevent him from employing Irishmen, Germans or even Chinese upon the same terms. And if it is done, and labor is thereby obtained cheaper than the citizens of this country desire to furnish it, the laboring class must not lay the charge to the capitalist who accomplishes it, but to the imperfections of our social and financial systems which make such resorts possible. Then, instead of committing this new national organization against any form of legal labor, its managers should have proposed remedies for the existing imperfections in our systems.

We are no special advocate of the introduction of Chinese or any other labor into this country; neither are we desirous of advocating any policy that will conflict with the interests of any laborer, but we are advocates, and always expect to be, of justice and equity to all people everywhere, because the time has come in the ages when we must begin to remember that we are all brothers under the sun, and that he or she who does not recognize and act upon this universal truth will, sooner or later, be obliged to learn it at the cost of dear experience. We expect to be found advocating very many of the principles laid down in the platform of the Labor party, and could wish that we may find nothing there adverse to the principles which are of general application. We desire to see the Labor interest advanced to the right and position of equality with capital, and we shall put forth our best endeavors to assist in this most just movement. At the same time we shall not commit ourselves to sustain or advocate anything that we conceive will be ultimately injurious to the true interests of humanity, or any part of it, therefore we shall at all times point out what we regard as errors in whatsoever this new party may endeavor to carry out. At the same time we shall, perhaps, be among its

firmest and truest advocates. The best friends are those who show us our faults and sustain us in the right.

NEW YORK, September 3, 1870.

PAPERS ON LABOR AND CAPITAL.

NO. IX.

This question forms one of the corner-stones of future society, but of all the questions in which society seems interested it is the worst understood. Four-fifths of the people of the world toil on, year after year, and all the time see the other fifth revelling in the luxuries the sweat of their brows has produced. While the one-fifth enjoy the luxuries thus produced, as though they had acquired them by divine right, which none may call in question nor dispute, the great power of the laboring many has never been felt. It has never been concentrated or organized into concert of action. Even now this immense force is still dispersed. It seems to have no centre around which it can gather. It has no organization, and herein lies its weakness.

Organization should be effected for two principal ends: First, for construction; second, for destruction. The old systems cumber the ground whereon the new must be reared, and they must be pulled down to give it room; nevertheless, the constructive part of the operation must first begin; before the old will yield, the new must at least be formulated. This is not impossible in the department of principles. This new rests upon foundations deeper down than existing things, and these can, therefore, be used previously to the destruction of the foundations of the old. The new also reaches higher than the old; hence its frame-work may be reared, while yet the old stand comparatively intact. The work of construction once begun, that of destruction must necessarily immediately follow, and when the former shall have been completed the latter will have been but finished. This is the philosophy of Integration and of Disintegration in all departments of the universe.

Labor and Capital is a question relating in the first instance to the material prosperity of a people; but secondarily it reacts upon all other interests—intellectual, moral, physical and religious. None of these interests can flourish among a people who are burdened by material wants; neither are they usually unitedly prosperous among that part of a people who are greatly advanced in material possessions. Either extreme in material interests appears to be deleterious to the best and most harmonious general advancement of all the other interests. It is the mean between the extremes—the calling up from those below, and the leveling down of those above the mean—in which the harmony of all is found.

Harmony of all the interests of humanity can alone be attained through organization. A permanent basis of organization can only be discovered by scientific investigation. The organization of society must be realized through the science of sociology, which, of all sciences is the least understood by the general mind. Yet there are among the great minds of the planet a large number of those who thoroughly comprehend this science, and it is to these that the world must look for a reconstruction of its society upon such principles as shall render it permanent; upon such, as it can constantly be improved upon, without changing its methods of operation.

Into such a reconstruction the branch of sociology that relates to production and use, or labor and capital, will enter largely, and must be the portion of it to be first entered upon, because all things which are built upon earth must have a material foundation until there shall be such a harmony and unity of interests, and such co-operation among mankind as would proceed from a universal brotherhood, in which each would have his special part to perform to contribute to the common result.

The agitation that is beginning to be felt all over the world where intelligent labor exists, indicates that the time is at hand wherein the first steps toward a constructive organization of society, upon scientific principles, is to be begun. Not only is this agitation shown to exist in this country, but it has lately been developed that labor societies exist throughout Europe, having a common head and centre, and that they deem themselves strong enough to express wishes entirely antagonistic to the ruling powers.

Now what these organizations require to become—something more than mere instruments for agitation, mere means by which the injustice between labor and capital is exposed—is to become constructive in their action; instead of expending all their means and strength in the work of pulling down the old systems of things, they should begin the actual construction of a new system. For this end they must bring science—the science of sociology—to their aid, and make its professors active leaders and trusted assistants in the grand work. Capital is putting forth some strong efforts to confine science in its interests, but the teachings of science are of too general and cosmopolitan a character to permit its professors to ally themselves with a pseudo aristocracy—the aristocracy of wealth.

Well may the political parties view with alarm the beginning of organization among the classes they have until now relied upon to carry themselves into power. If bereft of the capacity to influence the masses who heretofore have not thought for themselves, they know their power will depart. How has it been possible thus long for leaders to control the masses, except that the masses have permitted others to act for them, and that without rendering any account for such action? The time for such representation has passed. The people have arrived at that degree of understanding of their actual interests, that will not admit of a blind acquiescence in all that even a “People’s Congress” may do. They will begin to instruct their representatives instead of being led by them.

’Tis true that by capital coming to the rescue of the country it is intact to-day; but it asked its price and has been paid. So far the obligation is removed, and justice to all is demanded. Legislation entirely in the interests of capital will not be any longer tacitly acknowledged as binding those whose interests are sacrificed. Whatever obligations the country may be under to those who hold its securities, it is under still greater to the producing interest, to which it must look for the ability to retire them when called upon so to do by the tenor of the contract they contain. It thus appears that all the interests and all the prosperity of the country are dependent upon the producing classes, and therefore to them government must listen, for they will not be ignored much longer.

NEW YORK, Oct. 10, 1870.

PAPERS ON LABOR AND CAPITAL.

NO. X.

Production lies at the basis of all progress. Material production precedes all other kinds of acquirement. In the first degrees of social evolution, labor was merely to obtain the means of bodily sustenance and comfort; from this the present has widely departed; while the future must still further widen the distance between production as an end and production as the means to some end beyond. Production in early times meant simple muscular toil; it still means this, but also a great deal more; the proper direction of power makes it possible for a given amount of force to accomplish a greatly increased result. In the next century make proportionate rapid advancement in the better adaptation of means to ends than last made over the preceding, the direct application of muscular exertion to accomplish a material purpose will be almost unknown. Steam and water have relieved muscle of nearly all its most laborious occupations and increased the capacity of production a thousand fold.

The reduction of these powers to the uses of man will be supplemented by that of still more subtle and powerful agents to the same end, and this reduction will be followed by a proportionate relief to manual labor. The results of this advancement in the discovery of the means of reducing the elements of nature to the service of man, is to be revolutionary to the present grades and distinctions between the laborer and the capitalist—unless a proper understanding and application of the science of society first perform that inevitable result—which will guarantee to all individuals the possibility of like attainment in all things.

Science equalizes everything that comes within its sphere. Let the great scientist be never so destitute of material wealth, he is still the great man sought for and honored by those who have nothing but material wealth to recommend them. Any person may incidentally become wealthy in material possessions, but none but the devoted student of nature can become rich in mind; and, none but the devoted philanthropist can become rich in heart and soul. Even those who have immense earthly possessions, show their consciousness of inferiority by courting the great in other fields of acquirement. This alone should teach all people that true greatness is not to be gained through riches, and that these should only be considered advantageous as the means by which to acquire other greater riches and blessings.

The true uses of wealth are to advance the peoples of earth from the conditions in which they are to higher and better conditions, to those where caste and distinctions shall not be measured by it, but by the good that is accomplished by its use, in which he will be considered the greatest man and the most honored, who shall make the best uses of material wealth in benefiting humanity as a common brotherhood.

It has become too late in the ages for individuals to think of living for themselves, or even for those immediately connected with them. Mutuality of interest is spreading from family interests to world-wide interests, and the greatest minds of the present are those which perceive and act upon this fact. The leavening power of assimilation is rapidly at work among the nations, races and peoples of the earth. The electric telegraph makes it possible for all the different nations of the earth to be possessed of the same thought at the same time. For the last two months the minds of the whole world have been turned toward France, where the real contest of the future has but just begun. It is impossible for this concentration of mind upon one centre to be productive of anything but a growing likeness among those who are the subjects of it. All the discoveries in all departments of life tend to the same unification of thought

and interest. In this unification is contained the prophecy of what the future shall be when no individual, family, nation or race, shall feel that they can live entirely for themselves.

The lesson the present movers in labor reforms have to learn is that of harmonizing the interests of labor and capital by the demonstrations of science. Springing from a common source and tending toward a common end, humanity must learn to progress on its course according to rule, to law and the requirements of order. These sustain the harmonies of the universe, and should be never-failing authorities for humanity to pattern after. Those who achieve the greatest conquests are they who can bring themselves into harmony with the principles that govern the movements of the innumerable worlds, no two of which are ever known to disastrously cross each other's path.

The world is capable of producing luxuriousness for all its children. It is their fault that all do not have it. A very large proportion of the capacity of humanity for production is diverted from natural occupations by the illegitimate relations existing in society. A part live off of the vitality of the rest; the principal object of the part being to see how much of the fruits of the rest they can aggregate, either by personal capacity, trickery or cunning, or by ingenious devices of law formed and administered in their interests. A perfect equality and an equal justice condemns all such distributions of the fruits of the earth. If capacity for acquisition exist among a part of the people, government should interfere to stop its being practiced at the expense of others.

We are aware that this kind of social rule will be repudiated as an infringement upon individual freedom of action. In this connection, however, it must ever be remembered that the individual can never be greater than the community of which he forms a part; in other words, the interests of the community must always be superior to those of the individual, and when individual interests conflict with the interest of the community they must yield to the community. This principle is recognized in very many things in government; for instance, the public demands a common highway which must interfere with the rights and interests of individuals; the individuals are compelled to give way for the public, from whose adjudgment there is no appeal. To this rule of action all the relations of society must sooner or later become subject, and the sooner it is reduced to this scientific determining power, the quicker society will have begun a progress whose course need never be deviated from.

NEW YORK, October 17, 1870.

PAPERS ON LABOR AND CAPITAL.

NO. XI.

One of "our Fundamental Propositions" is the ultimate analysis of the perfected results of harmonious relations between labor and its reward. It is not laid down in any spirit of mere speculation, but as a mark which the human family is capable of attaining, and one to which it should aspire. Neither is it at all impossible with some of the present representatives of the race; but it is a natural and legitimate condition for society when it shall have become sufficiently "grown" to be possible of organization.

Organization is the first step to be made toward reaching such conditions as the proposition indicate. Simple individual exertion can never be constructive of society. Neither can the exertions of a great number of individuals become constructive unless their action is combined or organized in one direction and for the same purpose. Agitation must always precede organization, and hence it is that nearly all primary movements are simply destructive or disintegrating to existing conditions. A perfect system of society cannot be organized to conta in those who are under any condition of servitude other than is rendered by the collective number to the law or rule they shall formulate, to control these relations. A perfect system of freedom is one of the first essentials, and this must be regulated by an exact justice, as between a community of brothers and sisters. No ignoring of any part of the community, whether male or female, can exist The organization must recognize each and every member of the community, and they in turn must also recognize the organization which becomes the rule of government.

No one will attempt to deny but that there is sufficient capital or wealth in the world to enable every one to live in a palace; neither would any deny that the conditions of humanity would be very much improved could such a leveling down and such a leveling up, as this equalization would require, be attained. This cannot result from any arbitrary rule of force, but must be the result of the operation of the proper principles of law in the relations of society. It must emanate from a consciousness within society itself of the justice of such principles therefore the mind of society must be imbued with these principles; and to do this is the business of those who understand the science of society. It has been denied that there is a science of society. The recognition now that there is such a science, and the fact that the evolution of society thus far has been formulated under it, is a vast step toward a general recognition of it. When once it is generally received as one of the demonstrated sciences, there will be various attempts in all

directions to organize upon its not yet demonstrated principles.

Those who have followed these articles will begin to see that the attainment of great wealth will not constitute one of the principal aims of the society of the future. It will only be considered as a means to other and higher ends. It has not been until quite recently that the fact of continuous life has been any more than _theoretically_ received. The practices of mankind have been just such, and only such, as would obtain, were there no life after physical death, and they have lived as though the whole of this life should be devoted to purely material ends, to the gratification of physical desires, and to comforts and pleasures arising from material possessions. Since the conviction has been stealing into the minds of humanity that life is continuous, that death is simply a change of the conditions of life, and that the best wealth that can be accumulated in the material life is that kind that will make the best capital to begin the next with, there is a marked change in the community at large.

It is beginning to be realized that there is a great deal more to live for in this life than mere bodily satisfaction and accumulation of wealth—of money. Nor is complete luxury one of the most preferable of circumstances. It is not conducive, under present conditions, to the best and most rapid development of the true wealth of the soul, nor can it ever be until correct views of the uses of wealth more generally obtain than they do at present.

In a true condition of society there would be no such thing as wealth, in its present signification. It would be reduced to the requirements of men in obtaining better wealth for themselves, and for the diffusion of it among their kind. In this consideration of the uses of life, there is no more important feature of it than that of organization in all departments. Such organization as will dispose of misery, poverty, ignorance and crime. All these can be cast out of society; and it is to be sincerely hoped for, that there will be formed a political party having its basis in the necessity and the possibility of such a disposal. Such conditions cannot exist in the midst of a community without exerting their deleterious influences over the higher and better conditions. People lose sight of this fact, and in all legislation it is ignored. Government now has the power to take these conditions in hand, and none are more interested in having it do so than the so-called labor party. Why should not this party organize upon some such radical principles of reform that will reach the roots of the ills they feel society labors under?

The policy of a party that would be permanently successful must be one that will include all of the great principles of reform. If such a party is not shortly organized, there will be conditions developed which will make such a party a necessity, even without organization. It would arise as if by magic out of the conditions of the times, and leaders will rise and come to the front as though Heaven-directed, and they will be received by the people by acclamation. The force of elections will be dispensed with, and party trickery forever killed.

The whole substrata of society is in foment. The terrific strifes that have been waged, and are being waged, lift the weight from the strata, and it begins to rise into demanding such recognition as has not been accorded it. The “Moses” who shall divide the “waters of the Red Sea,” that separates them from their “Canaan,” will be their God-appointed leader, whom to oppose would be futile. Political parties have been in the hands of such leaders, and have been used for such corrupt purposes, that the people have lost all confidence in them, and they demand A NEW ORDER OF THINGS, in which common honesty may properly find a place.

Labor and capital, lying, as they do, at the foundation of present society, and as they will enter largely into all societies of the future, so long as material wants are conducive to the true interests of humanity, should receive such consideration at the hands of the present as will so arrange their interests that there may be no violent disruption between them, when present governmental forms shall change. The sphere of government must be enlarged and made to include very many questions which are now utterly ignored, before society can ever be considered as resting upon a surely permanent foundation. To arrive at this foundation is the first and most important step for humanity to take. All minor ones are insignificant beside it, because the corner stones of this foundation must consist of a perfect individual justice, which will not be inconsistent nor at war with perfect collective justice. This condition the present inequalities between labor and capital forbid, and hence the importance of their harmonization.

NEW YORK, October 25, 1870.

PAPERS ON LABOR AND CAPITAL.

NO. XII.

Perhaps there is a no more suggestive or instructive fact in all the realm of society than that the laboring classes are the liberal classes. It is among them that nearly all social reforms begin, and among them that all governmental reforms first find moving

power. The wealthy classes are systematically conservative; and by instinct they are opposed to all movements which tend to equalization. They are to social reform just what bigots are to religious liberalization. They adopt a creed which their practice is never to depart from, and it is only by the force of the large majority of the people combined against them that they ever do depart from them. The time was when it was the grossest infidelity to question any of the extravagant assertions contained in the Bible; but nearly all Christian sects now assume the right to place their own construction upon what is found therein. This construction is found to grow more human and liberal every year. Twenty years ago, the more “hell-fire and brimstone” a minister gave forth, the more Gospel it was considered that he taught. The same rule obtains in regard to all social questions, and the same rule of extending liberalization will continue, until the balancing point of equalization is reached, in which there shall be no power to determine for the individual, except himself or herself, what is for his or her individual good, or what to him or her is right.

Wealth, in its present position, is aristocratic; and Labor, in its present position, is democratic. Aristocracy always assumes to control that which is under it, in a material sense. It has always assumed this control, and whenever possible has exercised it. This assumption has been exercised so long that those over whom it has been swayed have come to regard it as something approaching a “divine right.” This condition of servitude was possible so long as ignorance possessed the masses over whom it sought control. When education began its silent yet potent work, the power of assumed “divine right” began to weaken. General education is all that the world requires to emancipate it from the rule of all kinds of aristocracy. Common schools for children, and the public press for adults, have done and are doing the work of emancipation.

It was not until quite recently that the representatives of labor began to know the benefits to be derived from organization. They do not yet know the full benefits which it is possible for them to obtain from it; much that they do obtain from it is, on the whole, deleterious rather than beneficial. They require more general knowledge. They need the aid of science to point out the paths in which they should seek to walk. Science, to the organizations of labor, is what discipline is to the army. Without it, the first is powerless, and the last dangerous to those who command and support it.

It is very much to be regretted that so much of bitter denunciation of the wealthy is heard among laborers. It shows that they, if possessed of the power, would wield it more despotically than it is now wielded by those possessing it. Force, as a regulator, can at best be but a mere temporary makeshift, which, unless quickly followed by justice in organization, degenerates into absolutism. This is the danger which it is to be feared would follow the elevation of labor into the position now occupied by wealth. Hence it is that it takes long years of disappointment to chasten the hearts of those who seek change, before the order of civilization will allow it to come in its fullest extent.

Could changes in society be arranged and managed as changes in other departments are, no danger would ever supervene. New railroad bridges are constructed before the old ones are removed, and throughout the process of change the trains continue their regular movements. So it will be with society, when science shall have so enlightened the people that they shall know just what they are preparing to pass to.

The Labor Party now desires to be elevated into political place and power; but have its advocates any well-defined ideas regarding the results which are to follow such a change in the administration of government? It is much to be feared that the same old story of “Make hay while the sun shines,” would be the ruling element. We would not have it understood from these suggestions that we are opposed to such a change as the success of the Labor Party would imply. Any change cannot be for the worse. Principle could not, in any event, be less the ruling power than now; nor could money buy more politicians than it does now. One has to spend but a “season” in Washington to convince himself that there is a deal more truth than there is vulgarity in the saying, that “money makes the mare go.” Representatives and Senators who prate with loudest mouths of patriotism and devotion, spend all their own money and all they can borrow to get to Congress, and retire to private life, having made a fortune upon “five thousand a year.” The inference is too palpably plain. It is not necessary for us to say that all such fortunes are the results of bribery and corruption, and their possessors public thieves, and utterly unworthy of the confidence of honest devotees to a popular form of government.

It is this species of corruption that is becoming a stench in the nostrils of all those whose patriotism is more than pocket deep. In its growth they see the process of national disintegration begun, which they well know cannot continue indefinitely without bringing destruction to our country. The almost criminal indifference with which the masses of the people regard these examples of the power of money over the consciences of those to whom they have intrusted their most sacred political rights, speaks badly for the safety of republican institutions, as now operated. A saving power is needed. Where shall it be sought? All true reformers are looking to the Labor party for it. Let it unite to itself the principle of equal rights, regardless of sex, and it will succeed. Then, if it fill its mission well, it will prove itself to be what the present demands, to crush corruption which is so rapidly permeating our whole

body politic.

NEW YORK, November 1, 1870.

PAPERS ON LABOR AND CAPITAL.

NO. XIII.

The principles which should regulate these two great interests are, even in this age of scientific attainment and philosophic speculation, very imperfectly considered and still more imperfectly understood. There can be no perfect practice of the true principles which should govern their relations until the practices of the peoples are based on the recognition of the fact of the common brotherhood of humanity. There are a few people now living who fully appreciate the relationship which exists between the peoples of the world, and who would regulate their conduct toward their brothers by the “Golden Rule.” All the governments of the world are in direct opposition to this rule; hence it becomes an utter impossibility for isolated individuals to practice upon it to any great extent.

It is an acknowledged fact that the world is gradually being evolved by the means of government; and that government was at first organized to control individuals who would otherwise have operated from their own standpoint for selfish purposes. This kind of control will continue to be exercised until government will be able to control all individuals to act for the general public good, and this again will eventuate in all people acting for the public good of their own accord, when government in its present sense and for its present purposes will be done away with.

The relations of labor and capital are most intimately connected with the frame-work of all governments, because they could not exist without their active support. The difficulty with all present systems of government is that they are built upon the supposition that capital is the primarily controlling power; while the fact is that behind capital labor stands first and strongest. As intelligence becomes more and more generally diffused the domination of capital over labor becomes weaker and weaker, and the dignity of labor more and more apparent, and, as a necessary result of the growth of this sentiment, labor is accorded more and wider privileges.

It is a singular fact, and one to be regarded with a feeling bordering on astonishment, that it is possible for all legislation to be either conducted in the interests of capital or controlled by it, when the capitalists of the country are to the laborers as one is to ten. The same principle makes it possible for one man to control a dozen horses possessed of a hundred times his own strength. It is the power of knowledge over ignorance. The horses on the one hand are ignorant of their real power and yield it obediently to the command of assumed authority. So, too, is it with the mass of laborers; they do not know their real power and they yield obedience to the power of assumption aided by a superior intellect.

It is for this reason that the general diffusion of knowledge among the common people should receive so much more attention than it has or does. Every child, whether born of wealth or poverty, should inherit the right from government of a complete education in all the important branches of education. Not only should they inherit this right but the government should see to it that the right is obtained, compulsorily if need be. The acquisition of knowledge has ever tended to the liberalization of existing orders of things, and it was not until something akin to its general diffusion was obtained that any adequate ideas of the advantages of freedom became fixed in the minds of the people. It was a grand—almost a fatally grand—mistake which the people made when they considered that they had obtained complete freedom when they emancipated themselves from the so-called “tyranny” of England.

First, then, and that which is the basis of all other tyranny, is the fact that man, individually considered, is, in the strictest sense of the term, a slave to the conditions of his existence. Whatever else he may be free to perform he can never be emancipated from the necessity of yielding obedience to the demands of this existence. In his ignorant, undeveloped condition, intellectually, he has been led to yield himself in obedience to others whom it seemed to him were able by their superiority, mentally, to better administer to these prime necessities than he could do it for himself. This was the argument for the continuation of slavery in the South. They said the negroes were better off than they would be if cast upon their own resources for the supply of the necessities of life. Many persons felt the strength of this argument and yielded to its pleading. It is the same principle—that of inferior intelligence yielding to superior intelligence—which makes the possibility of all forms of slavery. It is this principle which has made it thus long possible for government to be conducted entirely in the interests of capital.

But it is just at this point, where the beginning of comprehension on the part of the representatives of labor is, that the fallaciousness of this arbitrary form of control begins to be felt by the masses who have hitherto yielded to it. They begin to see that they obtained freedom from one “tyranny” only to yield themselves to another, less odious than it was from the fact that one was represented by one person, while the other is represented by numerous persons. In some regards the last condition is worse than the first; for in it there is nothing to guard the constant encroachments of the tyrant upon their “reserved” rights. They are constantly subjected to legislation which filches from them the last possible farthing, that it may go to swell the coffers of some wealthy individual or some obese corporation.

At present the indications are anything but favorable for the interests of the producing classes. It seems as though the representatives of corporate interests, in which large amounts of money are invested, are organizing to make a crusade against the present possessed rights of the producing classes, to the end that, by all corporate organizations combining and making their interests mutual, they may come into the position that shall give them supreme and lasting control over the destinies of the country. They behold with jealousy the attempts at organization among laborers, knowing that, if it is carried to its full results, it will compel equality of interest and obtain the means necessary to enforce it.

It is the age of rapid change. What it would once have required an age to accomplish, is now performed in a single night. It would not _be very strange_ should the interests of labor control the next Presidential election. One thing is patent to all, some great issue must come up which will be of sufficient magnitude and general importance to arouse the people from the slough of indifference into which they have fallen since the settlement of the slavery issue. It is also equally patent that this issue must be some new combat between some form of slavery and a growing freedom; perhaps a consolidation of the several questions of progress into one interest to crush out, at once and forever, the reign of conservatism of all kinds, and the substitution therefor of an enlightened freedom, to be governed, guided and supported by the lights of science which shall point the way to all things which ought to be obtained.

What the world needs to-day is, that science, supported by wealth, shall come into power. Could this be arrived at, the dangers and difficulties now hovering around the issues between the still captive and the interests of enslaved labor, would be dispelled, and society, without further convulsive efforts, could assume its uninterrupted march toward perfect conditions of existence. It is to be feared that wealth will not yield to science, and that it will endeavor to bring it under its sway to further enslave the “toiling millions” and make them minister longer to its despotism. Let this be as it may, the existence of government upon its present basis of liberty and equality depends upon its checking a power that is being organized to control it. The New York _Herald_, not many days ago, pointed out this danger, but did not warn the people that it was a danger, leaving each to gather his or her own deduction from the mere presentation of the facts. Subsequently, however, it said, editorially, as follows:

“Now it is possible the American people may not be alarmed at the probable effects a combination of the capital and influence of these vast railroad corporations may have upon the future of the country—upon the permanency of its institutions and the perpetuity of its political liberties; but, in view of possible contingencies, we think we are justified in cautioning the people against the possible creation of a railroad oligarchy here that may prove as dangerous to the nation in times to come as was the Southern cotton oligarchy in times past.

“This subject is one of considerable interest to the American people, and the elections of members to the next Congress should be graduated accordingly.”

It is the duty, then, of the New Labor Party to become the best representative of general reform and a wider freedom for all individuals, male and female, which freedom should have no limit except that which borders upon interference with the freedom and rights of others, or that would be detrimental to the common interests of the public if practiced. In the widest freedom there is the most virtue, because, under restraint, compulsion often passes for virtue, while its semblance only is there. Freedom stamps all that is genuine, and exposes and denounces all that is counterfeit and affected. Enforced virtue in any direction, except for the protection of the community, is not one of the principles of a free government; but everything that the government can do that will further the interests of the community, come legitimately within its sphere. And it is to this end and purpose that the Labor party should press its claims to recognition upon the representatives of labor.

The workingman makes the government, and therefore has it in his hands to unmake it. If the government is not what it should be, it is because the workingmen have permitted it to exist and not perform its duty. It seems, then, that the _main point at issue_ is, to acquaint the representatives of labor everywhere with their power; to make them recognize the fact that they, being the majority,

have it in their power to elect the men who will legislate in their interests, and, by so doing, do away with this insane denunciation of wealth by the mouths of those would-be leaders, who, to become leaders, would stir up any kind of strife, required to gain their wishes. Of all such, the Labor Party should beware.

NEW YORK, Nov. 10, 1870.

PAPERS ON LABOR AND CAPITAL.

NO. XIV

We have repeatedly appealed to the productive classes to arouse from the slough of trustfulness and indifference in which they have remained so long, and to bestir themselves about their business of governing themselves. Thus far they have utterly failed in all duties of self-government. They have nominally lived in a country which proffers equality to all, but under which proffering they have virtually surrendered themselves to be governed by the considered mighty few, who, for their own purposes, exalt themselves into the position of The People's candidates until office is obtained, when they begin at once to invent schemes for continuing themselves in power; or, if they know it is impossible to be again returned, they devote themselves to making the most of what time they have.

The present doings of the people's representatives, both State and national, are practically limited to getting the most they can for themselves and their friends, while the study of the interests of their constituents and the country is either entirely ignored or shirked to the greatest possible extent. Each year this condition becomes more and more the controlling element of Congress and Legislature, and unless soon remedied, it will lead the country on blindly to its destruction. This course being directly in the interest of special and favored interests, has the favor and support of capital, while labor looks on with the utmost indifference, and sees its productions filched year after year.

Capital, of the two, is the more foolishly blind to its future; for it does not seem to comprehend that with the continuation of this course must come the day of reckoning, in which the debit side of all accounts will be heavily against it—so heavily that it will never be able to satisfy the demand which humanity will have for it to settle.

This consummation may be averted, but only in one way. The laboring classes must exercise their right of self-government themselves, after the dictates of reason and common sense, and no longer blindly intrust their interests and the common interests of the country to the self-selected few who prate with so much volubility, and who mouth the "King's English" so furiously about their undying patriotism and self-denying devotion. It may be set down at once and for all time that the patriotism and devotion professed by this class of orators and statesmen will be certain to continue until after their election is sure, after which it will do to watch them carefully lest they may have entirely expended it in their efforts for election.

While we have urged the laboring classes to arouse, we have at the same time shown the necessity of complete and thorough organization, and we now further urge the absolute withdrawal of affiliation with any party, and the devotion of their entire strength to the construction of their own party, upon the principles of freedom, equality and justice for all, let them lead where they may. All that is required by them is granted in the present Constitution, though, perhaps, in some points, were so, blindly, for the time, but which are now made plain and clear by late events in some of our States.

It is time that active movements should begin to be made toward organization for the next Presidential election. Both political parties are manœuvring in every possible direction to gain advantages. If the Labor Party will act wisely it can take up one of these parties and incorporate its remnants before the election comes off. But if the class who should form this party will remain stupidly blind, and continue to maintain these virtually defunct parties by their strength, instead of constructing a new party of their own, nothing which will positively shape the future course of events can be accomplished. The old will simply be bolstered up for another term, and four years more of submission to the behests and dictates of capital must be endured.

There will be a desperate attempt made during the coming session of Congress by capital to obtain further, and greater and stronger hold upon the vitals of the country. Efforts to effect the perpetuation of the franchises it already has, it counts upon making, with certainty of success; but the very extent of its efforts which it will make under the knowledge that what is to be obtained must be so at once, will press it to such extremes that it will most probably defeat its own purpose. This event will be rendered certain if the Labor Party will take a positive stand upon its own ground, which will make effective the springing of some "mines" that are prepared, which will put their representatives in such a light before the country as will most effectually dispose of all selfish

schemes which are now afloat. Let it be seen that no shirking of duty is permitted on the part of pretended labor representatives, and also let it be seen that all who lend themselves to the schemes of capital are properly shown up to the country.

Our interests are great and our country is dear to us, for it has cost us immense treasure and blood. Is it not worthy of being defended from all schemes, when so much has been required to construct and preserve it? To the care of laboring classes its preservation is now committed. Will they prove themselves worthy of the high trust? Or will they sell their birthright for less than a "mess of pottage?" Is it necessary that some great calamity come before an awakening to the reality of the condition will occur? Let it rather be, that wisdom be gleaned from the sore trials and the desperate situation of our brethren in France, which shall teach the use to be made of possessed rights and privileges.

NEW YORK, November 18, 1870.

PAPERS ON LABOR AND CAPITAL.

NO. XV.

The New York _Sunday Despatch_, of the 20th inst., contains a lengthy, interesting and highly instructive article, based upon recent interviews with Thomas Hughes and J. P. Mundella, members of the British House of Commons, who are also workingmen and employers. They are strongly of the opinion that "strikes" were never productive of anything but damage to both parties, and that arbitration is the only reasonable resort for the settlement of all mooted questions between laborers and their employers.

As examples of the misery engendered by "strikes," several instances are quoted, among which is found that of the potters and moulders in the vicinity of London, which proceeded to the very last extremity on the part of the strikers. Arbitration at last was resorted to, and resulted in no gain of conditions to the strikers.

These facts go to show that the immediate purposes of labor organizations are detrimental to their true interests. They must acknowledge that they cannot compel capital to their terms, and that in moderate counsels and wise action they will be much more likely to find their interests advancing.

The ultimate purposes of the Labor party which are to obtain control of legislation, may be productive of much good, or may be made the most fruitful cause of national disaster. We have all the time endeavored to show that the real interests of both capital and labor lie in the direction of complete unity; and that although labor is now suffering at the instance of capital, that it should not be laid to the charge of capital that it is in position to thus infringe upon the rights of labor, but to the charge, secondarily, of legislation, which is performed by the very men whom the laboring classes do their utmost to elect to office: and, primarily, to the imperfections in our present financial and social systems, which must be remedied before any very great benefit can accrue to the oppressed conditions of society.

To accomplish what is required in order that labor may rise to an equality with capital, the laboring classes must become enlightened upon the principles of political and social economy. Revolution, which is threatened from some quarters, would only lead away from justice and in the direction of anarchy. We are sorry to be obliged to say that we can find but little in the present propositions of the Labor Party which promises very much of good. For the most part, its leaders are bigoted and cliquish to the extreme, possessing but little of the philosophic comprehension of the conditions through which labor must be elevated. Declaration of principles in series of resolutions which form a necessary part of all political gatherings amounts to nothing unless the party presenting them "squares" itself by them. This is the fatal error of all parties and all governments. They set out by making certain fundamental declarations, which they afterward endeavor to compel into meeting the exigencies of the times.

There is a great work the Labor Party can do. There are imperfections in our government, and these it should take up and remedy. It is a well-established fact, as every one knows, that a government that is not a representative of the minorities as well as of the majorities is not a government of freedom, equality and justice. If imperfections exist even in the much revered Constitution, it should not be held so sacred that none of its faults can be remedied. If there are inconsistencies in it, or if it contain provisions which the present has outgrown, let it be thoroughly amended, and as often as it can be, and made better. We do not believe in anything being held so sacred as not to be submitted to a complete analysis, so that it may be determined just what there is good, and what there is which can be bettered. We are inclined to the opinion that the whole Constitution should be revised, clarified and simplified, and made so plain that there would be no possibility of different constructions being put upon any part of it.

Our government should soon be so formulated, and the people so well informed upon the true principles of government, that all existing administrations should exist by the unanimous consent of all the people. The strife should not be for party, representing different principles, but for the best representative men to administer the Constitutional principles which all would be agreed upon.

There will a party arise having these objects in view, and it need not be predicted that such a party, once organized, will begin a new era in the history of governments, for sufficient comprehension of what the future will be exists to make this a foregone conclusion. The Labor Party should make itself that party. Has it the requisites?

NEW YORK, November 25, 1870.

PAPERS ON LABOR AND CAPITAL.

NO. XVI.

In the full and legitimate consideration of this subject the range should extend beyond the things immediately attaching to the capitalist and the laborer as persons, and merge into the question of Philosophic Equality, out of which consideration arises the true relations of the extremes of it represented by these two classes. Under a true republican form of government the inherent right to equality on the part of all its citizens should not only be recognized but guaranteed. Equality, except as a mythical name, does not exist in practice in this country; nor for that matter in any country, except where each individual is his own governor, to the extent of his power to maintain such authority; and each individual being possessed of this right to maintain it, comprises that equality. Philosophic Equality presupposes the right of each individual to exercise all the powers possessed by him, in which exercise the rights of no other individual would be interfered with, but which exercise should not be aided or protected by any device of law. The moment a law is made to assist an individual, or any number of individuals, in the performance of his or their undertaking, that moment equality on the part of all other citizens ceases. Not only is this true specifically, but it is a great deal more; it is true generally that if an individual or a class of individuals receive aid, comfort and protection from the law, in their pursuits, all other individuals of all pursuits are rendered unequal in their competition with them in all of their respective pursuits.

That is to say, if a person is protected in the manufacture of salt by the law, which imposes a heavy tax on all foreign salt imported into the country, the manufacturer or producer of grain is at once placed by the law in a condition of inequality with him, and in a double sense if he be a consumer of salt; for not only is the price of the home manufactured salt increased by the imposition of the tax, while the price of the home grown grain is not proportionately increased, but the producer of the grain is obliged to pay the increased price for the salt which he consumes. The same rule is applicable to all things wherein individuals are obliged to seek protection from foreign importations, to be able to produce the same at home.

The argument in favor of this course is, that while protection, extended to certain interests, increases the prices of their productions to the consumers of them, the consumers by it are also enabled to obtain higher prices for what they have to place upon the market. This is all very well so far as it has any application, but what is the effect upon the very large proportion of the working people of the country who are not producers of anything in their own right, but are simply laborers for such producers? If there is only an equality maintained to the employers of such labor, how can the benefit extend to the employed?

In making this complex argument, it is forgotten that real wealth and real prosperity do not consist in high prices for everything, but in the quantity which is actually possessed. Prices under protection must ever fluctuate, and a person rich this year may be rendered poor next year, by the depreciation of his property. Witness the fall of real estate in this city for an exemplification of what we mean. High prices are not the ultimatum to be gained by any people of any country; but, on the contrary, the true point to attain is the employment of the industry of a country in those directions, wherein _the most can be produced at the least cost_, in the accumulation of the proceeds of which the country, as a whole, must become wealthy more rapidly than in the pursuit of the other extreme, which is the production of the least at the greatest cost; or in any modification of this proposition.

The result of continuous protection to any interest of the country may be exemplified by the application of it to something which comes directly home to us. Suppose that there are some gardeners on the upper part of Manhattan Island who appeal to the city authorities for protection against the gardeners of Long Island, New Jersey, &c., because their soil being not so fruitful as that of Long Island and New Jersey, they cannot afford to sell their vegetables as low as those can be sold which are produced outside. Thereupon a tax of twenty-five per cent. is levied by the city upon all foreign vegetables sold in the market. The result is, that all purchasers of vegetables in the city are forced to pay the additional cost merely to enable a few insignificant persons to pursue a calling which they would otherwise abandon for some other which they could pursue without protection. This, though a common

illustration, exemplifies the operation of special protection in all its phases. It enables the few to pursue callings at the expense of the many without returning to that many any adequate benefit.

The trouble with our manufacturers is, that they want to get rich too fast. They are not willing to begin a new business in a way proportionate to their small means, and from this grow gradually into large producers as the manufacturers of other countries have done. They want to be able to employ labor and pay much larger prices than are paid to those laborers who toil in unprotected industries. Nor is the laborer any better off in the general result. The laboring classes of the country are not so well off under the present system of high prices as they were before the war, which indicates that the advance in wages has been more than counterbalanced by the increase in the prices of the laborers' necessities. As a general proposition, it is true that low prices are more favorable to the laborer than high prices; and that, under a system of protection to special favored interests, those interests become rich at the expense of the laborer; or, in more general terms, the rich become richer and the poor poorer with each succeeding year.

Such is the general argument against protective duties; but it does not by any means follow that all protection should be immediately abandoned and Free Trade become at once and fully inaugurated. This would be as grossly unjust to all these interests which have been encouraged into existence by the present system, as that of protection was to the common industries. What should be done is this: Unrestricted commerce, which would allow of the natural demands of a country being supplied, without restrictions of any kind, should be laid down as the true principle, and a gradual approach from present protective measures to freedom be inaugurated. No immediate jump—nor even rapid advance that would produce misfortune to any branch of industry, should it be attempted—but an approach, running through a sufficient number of years to allow of the adjustment of industries, should be the course. Under such a system all the various industries of the country would gradually equalize, and the laborers and employers in each would approach an equal footing. The farmers of the rich Western prairies would no longer be able to complain of the discrimination of government in favor of the cotton, woolen and iron manufacturers of the sterile East. Whether this policy is immediately adopted by government or not, it certainly will be, when the rapidly increasing West shall become the dominant power in it. Better that steps looking to it should be at once adopted than that it come after awhile upon an unprepared country, which course has been so often erroneously pursued to the destruction, demoralization and discouragement of those classes of industries which require consideration in their youth from the strong arm of the government; to accord which is not only for the interests of the country, but which is also its duty to its acknowledged citizens; the error heretofore having been that the consideration thus extended has been at the expense of a _part of the citizens_ of the country and not at the expense of the country as a whole.

Equality to all the citizens of the country can only be possible where there is no special discrimination on the part of government toward any, whether that discrimination is in the form of specific protective duties, unequal levies of taxes, or through devices of law; or, in other words, equality is an impossibility so long as special legislation is allowed either in our State or National councils.

PAPERS ON LABOR AND CAPITAL.

NO. XVII.

The great object of a republican form of government is to arrive at that condition wherein all the people constituting its citizens will stand upon a perfect equality in all things, which can be effected by government. A government cannot determine that each citizen shall have equal capacity to apply and make use of the rights, privileges and immunities which it guarantees to its people, but it can determine that each citizen shall have an equality of right to these benefits, the perfect attainment of which must rest with the citizen.

The question of Labor and Capital, as was said before, is included in the greater and more important question of a Common Equality, or an equality which is predicated upon the fact that all mankind are brethren. A republican form of government should find its fountain in this fact, and all its causes should be governed by its deductions. All the means of providing for the administration of the government, for its maintenance and for the correction of any existing abuses, should be formulated with this one greatest of all human possibilities ever in view. Thus formulated, its practices would ever tend to bring all the people into a comprehension of it, which comprehension is now scarcely existent except in meaningless words, which are dealt from pharisaical pulpits. In our last number the practice of protection to favored interests was considered, with reference to its general effect upon other unfavored industries; the unequal working of the system of levying duties does not stop with generalities; it extends and touches a still more vital point, and one which the people are more sensitive upon than almost any other. The laying of specific duties upon imported goods and wares is an indirect way of _taxing_ that portion of the people who consume such imported goods and wares. It not only

makes it possible for the protected interest to exist at the expense of other interests which consume, but by this operation the government obtains revenue which is an indirect tax gathered from those who are compelled to pay the advanced prices which the levying of duties implies. The amount obtained by such unequal and indirect methods of revenue for the last fiscal year was the enormous sum of $194,448,427, every dollar of which was in reality but an additional tax drawn from the individuals who purchased such imported merchandise. This manner of levying taxes would not matter so much as a system of taxation did it fall equally upon the taxable property of the country, upon which general taxes are levied, but nearly $100,000,000 of the above sum was collected upon woolens, cottons, sugar, molasses, coffee and tea, of all of which the poorest in common with the richest are almost equal consumers.

Laborers of the United States! How like you this manner of filching your hard-earned dollars, under the specious, fraudulent name of “protection to home industries.” It is no wonder that your hard-earned wages will scarcely supply your families’ necessities, when you are compelled to pay such a sum upon the most common staple articles of general consumption. It is no wonder you are continuously laborers, never being able to become producers upon your own account, when you, who should not, and, under general principles of taxation would not be called upon to pay a single dollar as a direct tax, are thus burdened.

Thus it will be seen that the levying of specific duties on imported goods is a most unequal and iniquitous manner of taxing the poor laboring classes of the country to support the government, which is administered to all intents and purposes in the interests of the rich, and under which the really poor become poorer every year.

Nor are the other means to which the government resorts to support itself entitled to very much more consideration than that of the indirect one just mentioned. There is no equality to the general people in any of them; and it is quite evident that the whole system of revenue for the support of the government should be remodeled, so as to fall where it should, in justice, upon the taxable property of the whole Union. This done, and a sound financial system also inaugurated, the lower classes of society would begin to be leveled up to the medium, and the upper classes to be leveled down to the same basis of material prosperity.

A system of taxation for the support of all government—town, city, county, state and national—should be formulated and inaugurated, based upon the proposition that all taxes should be general and none special. All of these taxes, for the several purposes, should be assessed, levied and collected by one set of revenue officers, and thereby an immense system of economy introduced, whereby the collection of the revenues of the country should not consume, by one-twentieth part, what is now consumed in the almost innumerable methods which are adopted to obtain the people’s money by indirect means. All of these subjects are for the laboring classes to take up, examine, decide upon and rectify, and never will they obtain the possibility of an equality until this is done. Never can equality be possible under the forms through which government is now administered and supported, and never will the laboring classes become independent of the wealthy classes until the freedom, equality and justice, which are the birthright of every citizen of the United States, become possible of attainment under its government.

PAPERS ON FINANCE AND COMMERCE.

NO. I.

In the following papers it will be our design to treat the questions of Finance and Commerce in a somewhat different manner from the ordinary and current way. The mere records of the transactions had in the world of money and of merchandise belong to the ordinary method of dealing with all matters that interest the people. The facts—the results—only enter into the consideration, and if serious conflict or serious faults are recorded, no attention is paid to the sources from which they spring, and from which they will continue to spring so long as the sources furnish the causes. All subjects, and all parts of the common interests of humanity, will receive from us not only the attention which the present demands, but if the present brings unhappiness to humanity, or does not bring happiness, the fountains will be examined to discover where the stream takes on its bitterness and its sediment—and, for instance, produces financial disease—with the view of exposing to the people what causes their unhappiness or lack of happiness.

As society is constituted at present, nothing within its interests has so much power for good or ill as money. He that has it is independent—is a free man; while he that has it not is dependent—a slave in some one or other of the forms of slavery. Men recognize that this is an imperfect condition of society, made up, as it is of people born free and equal in the eyes of the law, and by it entitled to their chosen path of happiness. These being the birthright of every one, the construction of society should be such as to guarantee it to every one. As society improves its condition, the advance made will be ever toward practical equality in all temporal things. It is the duty of those who labor in the interests of society to lay hold of the future, and bring its conditions into the

broadest present application.

Money being the corner-stone upon which society is now built, is thereby that stone of all others which should be perfect, not only in form, but perfect in duration: that is, it should be of such composite elements that time nor change should be able to produce any effect, either upon its external appearance or upon the arrangement of its parts. It becomes apparent, then, at first observation from this standpoint, that our present corner-stone is not one that can endure; it becomes plain that it not only will change, but that it should change, because of its capability to meet the requirement of a perfect corner-stone, upon which society can rest with perfect and continuous security.

Gold has long been the accepted money standard of value. Intrinsically, it has no value other than for the other uses to which it is adapted, but custom and long usage have raised it into the position of a god, before whom the world falls down and worships with as much devotion as Pagans do before their various gods. And, considered as a god, none other has in this day and age one-half the power, nor is any other worshiped with one-half the devotion it is. This may be considered an unjust reflection upon the so-called Christians; but let them, as a class, examine themselves individually, and if the analysis does not sustain the proposition, we shall be very willing to confess our error, and appeal for forgiveness. Gold _has_ been the accepted money standard, but the practice, since the depreciation of our country's credit, has, to all intents and purposes, reduced it to a mere commodity. Our money is not measured by Gold—Gold is measured by it. It may be said that this is merely for temporary convenience, but nevertheless it is so measured, and the practice has demonstrated that so far as facilitating exchange of products in our own country is concerned, its use might be dispensed with. If it can be dispensed with and trade continue, its importance as money entirely disappears. Would dispensing with its use offer any impediments to commerce with other countries? But this article is simply introductory, intended rather to indicate what our treatment of finance will be, than for the discussion of any of the questions that arise under it. These will remain for future consideration; here we will simply state that we do not believe gold to be a true standard of value; that we do not believe its use as money is at all necessary; that we do not believe that its use as money contributes to general prosperity; and that we do believe that its use will be supplanted by a new medium—the true representative of that portion of the real wealth of the country which is at the given time in the process of exchange.

NEW YORK, August 25, 1870.

PAPERS ON FINANCE AND COMMERCE.

NO. II.

Finance and commerce are so intimately connected that one cannot be treated without the other being, at least, indirectly alluded to. If these terms are analyzed, their relations will be perfectly understood. Commerce is the simple exchange of something one individual possesses for something another individual is possessed of. This exchange may be between neighbors, or between nations; it is all commerce. In ancient times, articles of merchandise were exchanged for articles of merchandise, but as commerce increased in amount, and its limits became extended, it became necessary to make use of something that should represent value, so that there need not, in all cases, be an actual transfer of property for property. The medium used to facilitate these exchanges was money in its first phases, and out of this necessity have grown all the different monetary devices made use of, at various times, in the history of civilization.

To demonstrate that money is only a convenience and not an absolute necessity, any one has only to observe that frequent purchases, sales and payments are made without the use of money or any other representative of value, but by the direct transfer of value for value. It is plain, then, that money, be it gold, silver or what else it may, if not intrinsically of the value set upon it, but that it represents something that has intrinsic value. If this is questioned, let any one who doubts it procure some gold in its original state and endeavor to make exchanges with it. He will find that no one will receive it, even at its value by weight. Were he to apply to a dozen places where gold, in mass, is dealt in, he would be offered a dozen different prices for his article. It is only after gold has passed through the hands of the government, and has received its impress as an indorsement, that it becomes current as money.

It is further to be observed that the time came when even coin became too burdensome to be directly transferred in making exchanges, and something representing it was brought into use. This consisted of bits of paper, containing upon them promises to pay so much in coin, &c., &c.; and under this practice banks of issue sprung into existence, their issues being supposed to represent a gold or coin basis of value. But a full representation alone of coin deposited was found not to supply a sufficient

circulating medium to accommodate the movement of produce, and for other uses, and it became customary for the banks to expand their issues beyond the amount of coin on hand, upon the supposition that these promises to pay would never be presented in sufficient quantities to consume their actual specie. But suppositions are only true _generally_, and hence it came that promises to pay often exhausted the ability to pay, and here began the ills that must necessarily attend a false standard of values.

In all seasons of financial distress, gold, as a standard, has failed. The necessities of our late war demonstrated and represented the fallacy of an absolute standard in gold, and happily suggested a better standard. No sooner did the supply of gold at the command of the government fail, than the latter was compelled to resort to its credit, or to a direct representation of the true value and wealth of the country. The credit of the government was the ability and intention of the country to meet the promises of its government, and this ability determined its currency. It was not the amount of gold, absolutely, that the country was supposed capable of acquiring that thus entered into consideration, but the ability of the country to produce certain quantities of merchandise, which should, in time, be sufficient, above consumption, to balance these promises to pay. It was the productive capacity of this country that gave value to its currency and bonds irrespective of gold. The productive capacity of a country is then the virtual standard of the value of its currency, and as gold can only be obtained by the products of the country, its necessity as a medium may be dispensed with. It is now predicted that the sooner gold, as the money god, is dethroned in the hearts and customs of the people, the sooner a sound and perfect system of finance will be inaugurated.

That there is a true standard of value, and one that can never fail in time of need, nor be made use of for speculative purposes as gold is, must be apparent to every thinking mind. How many of the people of this country, during the last eight years, have received gold or silver for what they have disposed of, or have used it to purchase their necessities? And yet the talk of a return to specie payment is everywhere heard. When will the idol worship of the god of gold be completely abolished?

NEW YORK, August 31, 1870.

PAPERS ON FINANCE AND COMMERCE.

NO. III.

We have said that there is a true standard of value, and that this is based in the capacity of a country to pay without infringing upon the country itself; that is, without resorting to an actual transfer of supposed title to any part of its domain for something the domain itself produced. Actual ownership in the soil of a country is an assumption, as has been stated in the “Papers on Labor and Capital.” If the title to any real estate is traced back far enough, it would be found to have originated in the practice of “Squatter Sovereignty.” The inhabitants of a country having the right to make use of the land they occupy, render it more or less valuable, according to the amount they can make it produce, whether it be in the shape of its natural products or those of artificial assistance, or whether it is simply occupied for purposes other than production.

The basis, however, of the value is in the productions of the soil of a country; it matters not how much value may be added by the art of man to what nature furnishes. This would find no scope for action did the earth not first yield the fruits of her bosom to the hand of the artist. The finest cloth, the most delicate silks and laces, the most costly jewels, even the light that robs night of its darkness, are all primarily the products of the earth. Without this yielding of the earth there would be nothing. This giving up of the earth to the demands, efforts and desires of man, is the process by which he acquires all his wealth. Even the gold that has so long been called money the earth has yielded, and still yields. When this is considered in its true light, we come to a realization that gold is no more money, absolutely, than any other of the different products of the earth, but with them all it forms the real value standard. Gold is relatively valuable for the general uses it can be made to subserve; so, too, and only so, are all other products. Any other metal might just as well have been selected out of which to coin money as gold. It no longer answers the purpose it has been used for so long. It is not “radical” enough to suit “the times.” It is one of the landmarks of conservatism, reminding us that once it required at least six months to communicate with, and receive an answer from, London, whereas we now know the 5 o’clock P. M. closing prices of stocks in London at 1 o’clock of the same day.

Such annihilation of time and space is entirely ahead of, and above, the era of gold, which must yield its sway to something more elastic, and consequently possible of better adaptation to the constantly varying requirements of the peoples. The world having been so long held in financial bondage to gold, is now approaching a period wherein it will rid itself of the yoke. A very few people in the world rule it. What of the thrones of Europe without the Rothschilds? and what of them if not for gold? The vast debts of those countries alone render crowns longer endurable. Just a little more intelligence among the common people—just a few more

newspapers and readers, and the work is done; those who play king, and they who are the real kings, will fall together. Kings rule the people, but money rules kings. This is beginning to be realized, and the realization is not satisfactory to those who produce wealth; they do not care to live under the tyranny of a god they themselves have fashioned. But after gold, what?

NEW YORK, Sept 7, 1870.

PAPERS ON FINANCE AND COMMERCE.

NO. IV.

If gold, as a medium of exchange, is behind the requirements of the times—and that it is has been pretty fully demonstrated—some reform should be instituted to supply the failure; some reform—not merely to meet the exigencies of present time and circumstances—which should be inaugurated as a permanent change.

Our government, during the last war, was obliged to resort to what was considered then by nearly all people, and is still considered by many people, as very extreme measures, in order to furnish the material by which the war might be carried on. Without the greenbacks we never could have succeeded as we did. To the person who conceived this project we are as greatly indebted as to our generals, who successfully prosecuted the war upon the means furnished through his financial foresight. This was one means of resorting to the credit of the country. If the credit of the country was sufficiently good to furnish it with the means to carry on such an exhaustive war as ours was, it surely should be good for any peaceful time.

For our part, we cannot see the propriety of returning to specie payment; and there is one insuperable objection to it. Gold cannot furnish the circulating medium for the world, and credit must be resorted to; and the necessity of having two kinds of circulation involves difficulties which the mercantile world would be glad to have forever done with.

Why should people be obliged to use one kind of circulating medium to purchase another kind with, and then use this second kind to pay his debts to another party, who will sell it again to obtain what the first person used to purchase it? This is the logic of specie payments. If it is argued that the actual transfer of the gold is not necessary, we would then ask why is specie payment desirable at all? The facts regarding this question are that people have become wedded to the idea that gold is the only possible thing that can be made money, while all their practice has been that it is the least entitled to the name of money of anything they have ever used as such.

As has been said, the real standard value of a country is its capacity to produce, and it is this production that requires to be moved, exchanged, bartered or sold. The use of something to represent this, for which it can stand responsible in general terms, is what is required of money. That kind of money which will best meet all these requirements is the best money. That kind of money which has elasticity, that will be plenty when business is active, and that can be readily put to other use for profit when business is less demanding, is the kind the prosperity of a country demands. With a money of this kind, all financial crises would be impossible. It is the possibility of making a stringent market that unsettles financial matters and causes financial destruction. And it is because we have not a financial system of our own that it is possible for exigencies in other countries to unsettle values here. To-day, the price of our securities in London determines the price of gold here. In view of the possible complications in which Europe is liable to be involved any time, and which she must within a very few years be involved in, it becomes a matter of considerable moment, whether our finances are to be governed and guided by the condition of things there, when these things shall come.

As a nation we are or can be, were it necessary, independent of the world, and are the first and best representative of a republican form of government. Why should we not be the nation to give to the world a reformed currency? The world—or that part of it which has grown to appreciate our kind of freedom—involuntarily turns its eyes to us for patterns of all things that a people during a change of government require. One of the first things a government requires is money. Why shall we not show the nations how to make the best use of their means, and give them a system that will do more for them than any system that has yet been tried, and by so doing also meet our own needs?

The capability to do this would instantly place us at the head of nations, and financially to stand thus, is to complete the measure of our greatness. Politically, we can never be subdued. During our late war there were two millions of men under arms. Just in this proportion, also, should we be powerful financially, and to become so would be to be allotted by the world the lead of it and all its nations.

PAPERS ON FINANCE AND COMMERCE.

NO. V.

The gravest of all questions of political economy is that of a country's money. A very great deal more of the people's common happiness depends upon money than even political economists generally suppose. Happiness is very closely allied to prosperity, and general prosperity in a country can never obtain unless it is under a sound financial system. Very few people understand what general prosperity means. It does not mean vast sums of gold in the hands of a few of the inhabitants of the country, while the great majority struggle month after month for the absolute necessities of life. There may be a great deal of money in a country and still be very little general prosperity with the common people. The question of money has never been considered philosophically, nor with due regard to the common interests of humanity. It is always viewed from the standpoint of the wealthy, and usually by the wealthy or by those in their direct interests.

The producing classes, however, are beginning to awake to the fact that they have never been represented in any of the legislation that has been had regarding finance and the currency they have been forced to use. On the contrary, they perceive that all legislation has been in the interests of capital, and this perception is what is arraying these supposed two interests against each other. The facts existing have only to be considered to prove that our financial system is unsound, and this should be sufficient to force our legislation to take up the question, and to handle it in the light of the demands of the present, utterly regardless of the superstition that has so long existed about the gold idol.

The objectors to any thing as money but gold, make much of the need of it to make good the balances of trade between different countries. But these forget that gold is nothing but merchandise until the country has placed its indorsement upon it, and that it is this which gives it the character of money, and that it does not derive this character from the fact that it is gold. The indorsement of a country upon gold coin is a simple guarantee that it is of a specific purity, after this, its value is determined by its weight. Thus gold sent to other countries to pay balances against us, is sent and received, as so much by weight of a specific quality of gold, and not as so much of our national money. The force of this objection, then, is utterly destroyed by these considerations; and especially so, when this same gold, coined by our government, is recoined by the country we send it to. Here it is distinctly proved that gold is not money, and that it is only a commodity which we produce and part with in exchange for other commodities, and that it is just as valuable for this purpose if it goes direct from the mines where we produce it, to other countries, as it is if it goes by the way of a United States Mint, where it receives the indorsement of the government.

To go still deeper, there is a no more mischievous idea than that all paper money should be redeemable in gold which should alone be legal-tender, because everybody knows that the amount of currency this country demands cannot by any possibility ever be redeemed by gold. It may be redeemed by using the same gold coin over and over again, as it is again and again received and paid; but just here is the difficulty; for ten dollars of currency in reality have to be redeemed by the one gold dollar. This is the _practice_ of specie payments, and a most mischievous one it is, too; it is the sole idea that leads to great inflations, and consequently to great collapses in finances and values. Under this system there never was nor never can be a reliable mercantile value to anything. Fluctuation is its direct result, while speculation, without this, would cease, and the vast horde of mere speculators who spend their whole time in it, would of necessity be compelled to become producers of some kind. It will thus be seen that the first principles of economy are in direct opposition to the results coming from the use of gold as money; and that these declare that something should supersede its use as such that it would be impossible to speculate upon; something that would have such absolute and never varying value as could be positively counted upon to endure a month, a year, a century or a thousand years, as the cases in question should respectively involve. Such a substantial thing might with propriety be called money, and in comparison to it gold would sink into utter insignificance and be forgotten.

NEW YORK, September 14, 1870.

PAPERS ON FINANCE AND COMMERCE.

NO. VI.

A very fallacious argument has been the rule, because gold has been considered "money," that all currency is "credit;" this at first blush would seem to be still further strengthened by the proposition that gold is only merchandise. By no means, however, is all currency credit. All bank currency is credit. All currency that is not legal-tender for contracts and debts is credit; but a currency

which is of itself legal-tender is money, because it is itself intrinsically valuable. All the uses one has for money it fills; it not only meets all demands that “credit currency” can meet, but it fills other and specific demands that bank currency cannot. It is receivable for nearly all governmental demands upon the people; it pays taxes, and cannot be refused by any one in payment of contracts and obligations. Such a currency has all the features and characteristics of money, except that in our practice it has not been receivable for duties upon imports. Had greenbacks been made legal-tender for all governmental purposes, they would have been “real money,” having intrinsic value, of which nothing short of the absolute destruction of the country and death of its inhabitants could have robbed them. The gold fallacy, however, prevented Congress from seeing the real drift of what they did, and the country, therefore, must yet a little longer be blinded by the thought that gold is the only money.

The only argument which is at all tenable, that converts anything that has all the qualities of merchandise into a measure of value is, that the article thus rendered costs at all times, and in all countries, the same labor to produce it. This test, every one knows, is not applicable to any single thing the earth yields; and as little as to any other does it attach to gold, and, therefore, gold in itself is subject to fluctuation, and can in no sense be considered an absolute measure of anything. This country, since California began to yield her gold, has been a great producer of the precious metal; that is, a certain amount of labor has produced a larger proportionate quantity of it than has generally been produced in this or in other countries; consequently we have been large exporters, not of money, but of gold, in its character as merchandise: very much of this has been exported in mass, uncoined, in which condition not even the most rigid gold stickler will pretend it is money.

Hence it follows that we do not need “money” to balance our accounts with other countries; we need particular kinds of merchandise which we have in larger quantities than we have use for, or which other countries need more than they do some merchandise they have which we require more than they do; which system brings about exchange, the sum total of which is commerce. If commerce were left to regulate itself without any interference to prevent the natural flow and reflux of the products of the earth, as stated above, there would soon become established permanent courses for certain products, to take which would still further localize all kinds of labor, and render each of nearly unvarying profit. It is this interference with the natural demand and supply of the various parts and peoples of the earth that breaks down the equilibrium of labor, and makes possible the extreme unequal distribution of wealth.

It will be seen that all questions of finance and commerce are intimately connected, while those of labor and capital grow out of the conditions they make possible and inevitable. To properly understand the relations of capital and labor, and to harmonize them, demands a correct comprehension of the basic principles of economy which relate to finance and commerce. If these were based in correct universal principles, there could be no questions to settle between labor and capital. Hence it is that it becomes specially requisite at this time, when labor is rising to a sense of the unjust position it is confined to, that these questions of finance should be agitated as the most important ones for adjustment. To begin at the root of the evil is the philosophic way to deal with all the ills of society as it is with all ills which result in the gradual evolution of all departments of the universe.

For a measure of value and to aid exchanges, then, there is required a currency, or medium, that does not possess any of the characteristics of merchandise, that is not a commodity nor a product in any sense of those terms, but something that has intrinsic value of itself, being a true representative of value, and of equal and absolute value at all times and under all circumstances and changes. Such a thing would be money, and anything not possessing these requirements is not worthy the name of money.

The question arises, then, Can there be anything formulated or brought into use that would possess all these requirements under all circumstances? It is quite certain that there never has been, as yet, anything used as money that was as absolute as a dollar, as a pound is as a pound, or as a foot is as a foot. A pound is just a pound under any and all circumstances; so, too, is a foot under the same; and so is a gallon, and so is a cord of wood; whether a greater or less number of any of them are required at one time or another for use, they are always a pound, a foot, a gallon, or a cord, and no more nor no less. Now, what we require is a measure of values of just as fixed and absolute a character as any of these. When this is acquired, then just as unvarying value will attach to the measure of values as there does to those measures. Money is but another name for values, and the dollar is one of the divisions of its measures. There is no more reason why money should fluctuate in its capacity of measuring or of being measured than there is that the foot should grow longer or shorter, or the pound greater or less, and there is just the same reason why it should not.

Then, the products of the earth once placed upon this unvarying standard, the cost of producing each different product would determine its exact value, and in time the producers of each kind would be upon an exact equality in regard to the value of their products. It is the attaching, in practice, of absolute value to something that can have no absolute value which makes possible all

the various degrees of poverty that belong to the laboring or producing classes. If these inequalities are to be remedied, there is but one method by which it can be done—that is, to reduce our money systems to the same fixedness that we have reduced all our other systems to. This once done, all labor will gravitate to an equality, and capital will become its best ally instead of, as now, its apparent enemy, while each of these interests, and all divisions of each of them, everywhere in the world, would become mutual, and by so being would prepare the way and lay the foundation for that grand harmonization of society which must precede the practical co-operation of mankind, as brethren, under a universal unitary government of the United States of the World.

NEW YORK, Sept. 20, 1870.

PAPERS ON FINANCE AND COMMERCE.

NO. VII.

The point has now been arrived at where it is to be considered as decided that gold is not, cannot, be money; that it is a valuable article of merchandise. Its utility beyond this character has not only departed as a principle, but in practice a very considerable portion of the most enlightened people in the world consider it the source of great mischief, and the more the causes of the financial ills we are subjected to are analyzed, the more they will be found to be dependent upon the attaching of a specific value to something that is as changeable in cost of production as it is possible for anything to be.

The philosopher and the best reformer would here step in and say that it is their province not so much to tear down the old as it is to prepare the new that shall take the place of the old. This is the science of all reform. However, before there can be a field prepared in which the new can be used, the defunct condition of the old must be pointed out, and its _debris_ cleared away, so that the new may find space for operation.

This preparation has in reality been already made. The necessities of the Government in the late war broke the first ground for the consideration of this very important question, and prepared the minds of the mass of the people, though, perhaps, unconsciously, for the reception of the idea that it is possible to do without gold; that specie payment is by no means a necessary accompaniment of a sound financial condition, and that a money system which is made dependent upon a redemption by something else, is not only not to be desired, but that it is the real foundation for all financial disasters, because it makes an undue expansion possible. The people who would once have considered a proposition for an irredeemable currency with the utmost alarm now discuss it as one of the things that is sure to be. It is believed by those who have studied this subject deepest that the time has arrived when this government must enter upon the consideration of a permanent change in our financial system, and that a return to the gold standard would be a disaster.

But, says the objector, how can an irredeemable currency ever be made to adapt itself to the varied demands of the country? How can anything so unsubstantial as a paper currency, without gold support, be made as absolute a measure of values as the yard-stick is of distance? and, if this can be accomplished, where will the elasticity of the currency be found? In general terms it is assumed that, unless the proposed financial system will answer all these conditions—that unless it will be elastic, adapting itself to all the demands that can be made, be they great or small, and at the same time remain absolute in its value, it is not even fit to be thought of, much less to be seriously considered as a substitute for what has been.

And this brings us back to the beginning of the argument—to the point from which the first departure was made. The course that will be pursued, however, after leaving this point this time will not be that of reconnoitring—looking over—the ground to be covered, but a steady, firm and final advance directly toward the objective result desired, which, if a failure is made in reaching, the campaign against gold may be considered a failure. Under the system of currency being good only when it can be redeemed by gold, there is required, to make the currency actually in circulation good, just as many gold dollars as there are currency dollars—that is, if there is at any time in circulation any more currency than there is gold to redeem it, then there is an expansion, which any sudden change in any of the circumstances by which nations are surrounded is liable to convert into a collapse. So long as everything is prosperous, so long as nothing arises to shake the confidence of the people, or to call the attention of any considerable number to the possibility that there is not gold enough to redeem all the currency that is in circulation, so long everything goes well; but so soon as any one of said conditions occur or change, then there is a rush to see who shall get what gold there is; the supply exhausted, the unredeemed currency is valueless. This is the practice and the result of a redeemable currency; the same results will also follow so long as such a system is tolerated.

Everybody knows that there never has been a currency in circulation sufficient in quantity to meet all the requirements of commerce that had a complete basis in gold, and everybody also knows that there is not gold enough in the world to meet this specific requirement. Hence it is that institutions possessing, say $100,000 in gold, put forth and obtain interest upon $500,000 in currency—that is to say, with a real capital of $100,000, which is worth six per cent. interest, they really obtain thirty per cent. interest, thus making it possible for them to double their original capital every three or four years. Did those who now so loudly complain of the National Banks receiving interest from the government upon their bonds deposited, and from the people upon their circulation, ever object to the greater enormities of the specie-paying banks?

The only use of money is to facilitate exchanges of what the earth produces, voluntarily or under compulsion. Money, then, has its direct relation to these products as a whole, and can have no special relation to any part of them; if made to enter upon and sustain any such special relation, it is a purely arbitrary law, without foundation in principle, that compels it, and all arbitrary laws belong to the ages past, when brute force was required to guide ignorance; they cannot be long in this age without generating irritation, and such irritation is now being rapidly developed all over the world, wherever the laboring classes have become at all advanced in knowledge. The few can no longer control the many; the many are to control the few. Capital, through false systems of values, has been able to control labor; but the time has nearly come when the producing many will control the accumulated wealth of the world for the benefit of the whole world—not simply and only because they are the many, but because they are to be reinforced by the invincible powers of demonstrated science, which are always to be found operating for the “greatest good for the greatest number.”

NEW YORK, Sept. 27, 1870.

PAPERS ON FINANCE AND COMMERCE.

NO. VIII.

Money was invented as a method to facilitate the exchanges of the products of the industry of the world. If this is a true definition of money, the only legitimate money it is possible to have is something that naturally grows out of the uses it is required for. A national currency, then, should be a representative of that which it is its sphere to exchange; that is to say: a currency dollar should stand for a certain amount of the different products, which have been produced at the expense of a certain amount of labor. It will be perceived that this representation is upon an entirely different hypothesis from that of a currency which is supposed to represent gold.

To begin with something which everybody can understand: It may be supposed that a farmer, occupying a given quantity of land, can, in a series of ten years, produce an average amount of ten thousand dollars per year to dispose of commercially. During the process of production he is obliged to have, say, eight thousand dollars’ worth of means to enable him to continue the process. Now, instead of his being obliged to obtain credit based upon his prospective crop, he is supplied with a representative currency based upon it; this enables him to purchase from time to time that which he requires. When his crop is harvested, it is disposed of, and his currency is _redeemed_ by it.

Now, make this application general to all kinds of production in the country—which is the only basis of value a country can have—and make the government the appraiser of the value thereof, and the maker and utterer of its representative, and a currency will be obtained that will possess all the requirements and characteristics of money; because it will be used to exchange that upon which it is based and of which it is representative, and which is substantially redeemed every time it exchanges any products of the country.

Now, how shall this system be instituted? In the census now being taken, the value of the total products of the country can be arrived at, which sum total should be used as the basis of issue, and continue as such during the next _ten years_, at the end of which time the increased products would require another valuation to amend the bases for an increased issue for the next ten years.

A currency thus obtained would possess all the substantial value that could be required of money. It is really the basis of value when gold is used; for how are a people to obtain gold unless they have produce to exchange for it?—which operation is, in reality, nothing more than the exchange of one commodity for another, of which it is not and cannot be representative, while in the case of the proposed currency an exchange is effected for that of which it is representative.

In this view of currency for a country, our system of greenbacks come nearer being money than anything that has ever been in use in this or in any other country. They were based upon the capacity of the country to produce, and had the government confined itself to their use, and had not been obliged to invent some further means to predicate securities, we should now have had a real money currency. Who is there to find fault with “greenbacks” as a national currency, provided there are enough of them to transact the business of the country with, _and no more than just enough_? But they lack one essential quality of real money—they are not receivable for all things that people need money for, and which the government demands of the people. They should have been made receivable for all government demands, _even for duties on imports_. But the necessities of the government, which was then struggling with all its might for existence, made it a “military necessity” to exact gold for duties on imports, as an indirect way of taxing the people who could afford to indulge in the luxuries of foreign products.

Though not available for duties there never has been in the history of the world so stable and invariable a measure of value as the greenbacks, since government ceased issuing any more than the amount already out. There has been no great financial panic and no considerable unsettling of commercial values. They require that one thing more should be done—they should be given a _fixed measure of value_. Then nothing more could be required of a currency than would be found in the greenbacks.

The reason, and the only reason, why the people can feel that such a currency may be unstable is the fear that the government may be induced to issue it in greater amount than primarily authorized, and consequently that it would depreciate; but this could not be until the nation should issue more than the value of its property. But for this deficiency there is a good and sufficient remedy, which can be provided and used in connection with the proposed new currency, which is to be based upon the capacity of the country for production, and which will also provide for different seasons or parts of seasons when more or less circulating medium is demanded to fulfill the business indications of the country; and with this it is believed all the objections are covered that can possibly be raised by the most strenuous stickler for a currency with a gold basis, though the government may issue never so great a volume of the currency proposed.

NEW YORK, Oct. 3, 1870.

PAPERS ON FINANCE AND COMMERCE.

NO. IX.

There are several propositions which should always remain in all considerations about money, so that the mind may not be led from its true sphere, and so that it may not be invested with peculiarities and characteristics that never did nor never can belong to money:

First and most important—most important because it is the determining point which gives all that follows tangibility—is, that _money, in its primary uses, is a means and not an end_. It is a means, because it was invented to assist the people in performing something that could be performed without, but not so well without it. And this is the _sole use_ of money. Because this has been lost sight of and it has been invested with other functions, it has been possible for it to be converted to uses which at times, in culminating, have almost turned the world topsy-turvy.

Second. Money is the medium of exchanging commodities, and when diverted from its legitimate use and is made an end, results will ever follow which _must_ be detrimental to the general interests involved.

Third. All the material value money possesses is so possessed because of the relation it bears to commodities, that relation being representative of or standing for.

Fourth. While money is the medium of exchanges, and while it is in use representative of valuable materials, it is in its _last_ analysis the _objective_ of that department of life of which labor is the _subjective_, and, therefore, when scientifically viewed, it resolves itself into a principal which is one of those upon which society must be built when a perfect foundation is formulated.

In providing a currency, therefore, to meet the uses which are demanded of it, its _scientific_ feature, as a principle, should be the point of departure, and should be the only guide until it is attained. Labor being the basis of production, is the positive power which reaches forth and expends itself, where money, the other pole of the social battery, is reached; this reaction upon labor completes the circuit, and here is the process which is continually going on: A certain amount of labor—a positive power—produces a certain amount of money or negative result The interference with this natural process by extraneous means, through which undue quantities of negative forces are accumulated, is that process which robs labor of its natural and, therefore, just results.

The labor which the people of this country are capable of performing, then, is the real basis upon which money should be formulated, and, as in practice, the results generally are annual in their return, this basis should be measured by all they can produce annually. It follows that the basis upon which money should be uttered is this annual capacity of labor, and there should be sufficient uttered to completely measure this capacity, between which two, when once established, there would be an equilibrium produced, which would only require to be permanently regulated and maintained to insure a perfect harmony in the material interests of society.

For example, let it be supposed that the extremest legitimate amount of currency that would be warranted under the previous rule is one billion of dollars; and that this amount is all that the uses of money require when there is the largest amount of business being transacted. It must be remembered that this is not a redeemable currency, but that it is money; that it is the representative of the wealth of the nation, and that the government, as the head of the nation, has uttered it, upon the soundest and best basis of value any money could possibly have—the productive capacity of the country. In this money system there could be no such thing as the failure of banks to redeem their issues; nor of any loss to be sustained by the individual because of the mismanagement of any board of directors; and what is more than all the rest, in the present systems of society, its value would be sustained by the collective accumulated wealth of the whole country, and it could by no possibility depreciate in value so long as the value of the country was not exceeded by the amount of the issue.

To guard the people against all apprehension of such a result ever being possible, there should be a measure placed upon this currency that will at all times make it just as absolute in its measure of value as the pound is in its measure of weight, or as inches are in their measure of distances. Though this is comparatively a new proposition, and one that but very few minds think a possibility, it nevertheless is just as possible and just as essential—and more so—as all other absolute and arbitrary standards are, that have been invented to give regularity and stability in their respective spheres of use.

This currency—this money—should be made convertible into a United States Bond, which should bear such a rate of interest—say four per cent.—as experience has or should demonstrate to be the true point of balance; and the bond should also be convertible into the currency at the option of the holder. The rate of interest should be open to readjustment every ten years, when the estimates for the currency are made. Thus it would come that whenever there should be so much currency in circulation that it would be worth less than four per cent. for business uses, the surplus would immediately be converted into four per cent. bonds; and whenever money for business should be worth more than four per cent., the bonds would be converted into the currency in just sufficient quantities to meet the demand and to restore the equilibrium.

It will be readily seen how perfectly this meets all the requirements of money, and how perfectly all the irregularities of demand and supply are met by it. Thus, when business is dull, and but little money is required, it (the surplus) will be in bonds drawing four per cent. interest; the moment business revives, the bonds will be at once converted, and the currency will meet the demand, and thus the constant conversion of the one into the other will regulate and maintain the equilibrium that all previous systems of money have so signally failed to do.

In our next the advantages of such a system will be still further considered and expounded, so that every one may be able to comprehend that a money system is possible of invention, upon which foreign bankers can not play their long-practiced games to any further one-sided advantage.

NEW YORK, Oct. 11, 1870.

PAPERS ON FINANCE AND COMMERCE.

NO. X.

The advantages of a currency which, instead of possessing the capacity of redeemability, is at all times convertible into something that is itself productive, cannot fail to be appreciated by all who have given any attention to the science of money. Theories regarding this branch of social science have been about as destructive to the proper development and understanding of the science as religious theories have been to that of a proper appreciation of the functions and the benefits of religion. The last have at all times stood in the path of progress. So, too, have the first. And for this reason are we to-day almost at the mercy of those who are possessed of the accumulated wealth of the world, which in combination would be a power sufficient to control all government in its interests, and thus it would be enabled to bring the world again under a despotism to which that of past despotism would hold no

comparison.

In such a money system too much circulating medium could never be uttered, for the moment a surplus quantity over the demands of legitimate business was in circulation, that moment it would begin to be converted into the four per cent. bonds; so that if there were two thousand millions uttered, it would always be worth just four per cent.; and if there were but five hundred millions uttered, it would never be worth any more than four per cent. Thus it is plainly to be seen that the government would always be necessitated to provide just as near the amount of circulating medium demanded as it would be possible to arrive at, _and no more_; for on any such surplus it would, as a matter of course, be obliged to pay the interest provided, which thus becomes the absolute measure of value that money requires to make it substantial, and which is required to deprive it of that capacity for producing great commercial inflations, which, in the financial history of this country, develop and burst about every second decade, and which produce not only the complete destruction of all purely speculative enterprises, but also the most wide-spread and fearful demoralization in all legitimate business.

Under such a money system, speculation, with all its accompanying demoralization, would rapidly depart from all classes of society. It is a notorious, yet unappreciated fact, that speculative enterprises lie at the foundation of all financial disorder, for which, if a remedy can be provided, the very considerable talent and time which is now devoted to it would be turned into channels of general usefulness and productiveness. Production is the foundation of all wealth, and, consequently, to increase wealth, production must be increased. Speculation is that spirit which constantly saps the vitality of wealth, and, therefore, society has no greater nor more debasing enemy than speculation.

It may be objected to by some that speculation leads to national development; that in many of the wild railroad, emigration, city and other schemes, that have been projected and carried through under its stimulus, the welfare of the country has been subserved. To this ingenious objection it may be answered that, under a sound financial system, these enterprises would have been undertaken everywhere when the demands of the country warranted them, and because there was a demand for them, instead of for the pure purposes of individual or corporate speculation. One of the best results that would flow from this change of incentive would be, that no “Bubbles” could be palmed off on the unwary by “flash” advertising, which would burst at some future time, to the destruction of some deluded victims of unscrupulous financiers.

It is one of the most fatal of commercial errors to suppose that large general prices are an evidence of prosperity. On the contrary, it is true that when the prices affixed to any kind of property are larger than its real capacity for production, it is an expansion which must at some time collapse, to the detriment of the holder. Thus, whenever property is valued at such a price that it cannot be used to pay a certain per cent. income, its value is expanded, and though this expansion may continue under the pressure of a so-called prosperity, and become general, even country-wide, if the general productive capacity of the country cannot sustain this increased value, collapse must as surely come as results follow causes. Even in this demonstration it is conclusively shown that the productive capacity of the country is the _real_ measure of value, and that, _finally_, no matter how irrelevant the process of wealth and prices may have been to it, _it is the power which ultimately measures all values_.

This appears to us such a plain proposition that it seems almost superfluous to present further arguments to prove the desirability of at once proceeding to make the productive capacity of the country the basis of value upon which to issue a currency to meet the legitimate demands of the people for the purposes of exchange. The attention of all who realize the unstableness of our present system, and the desirableness of providing against the tremendous fluctuations it is capable of, is called to the necessity of uniting to bring this matter prominently before the NEXT CONGRESS, with the view of having it thus brought prominently before the _country_, and of having it thoroughly analyzed and understood. When analyzed and comprehended, the idea of a _gold basis_ will forever depart from all progressive minds, and the impetus the new money system will thereby receive will never be checked until its science is developed into general national practice.

NEW YORK, Oct. 27, 1870.

PAPERS ON FINANCE AND COMMERCE.

NO. XI.

In our last, the necessity of urging the consideration of the finance question upon Congress, with the view of having the whole range of the matter brought prominently before the country, was proposed. Of all practical questions that require immediate solution, none is of so much importance to man as this; and none more so to woman unless that of equality for herself is. No

country can enjoy a series of years of uninterrupted commercial prosperity when that country has a circulating medium which can be affected by the manipulations of shrewd financiers for their own ends. And no financial policy is more ruinous to the true interests of a whole country than that of a constantly changing commercial valuation upon either personal or real estate, excepting alone in the latter, when it becomes the location of more capacity for actual production.

Real estate, abstractly considered, has no appreciable value. It only becomes relatively valuable when labor can make use of it to produce something valuable from it or by it. Absolutely there can be no individual title to any part of the soil of any country. Taken as a whole, the land comprised within the limits of the authority of any government can be made such use of as such government may determine, but as to actual conveyance of absolute individual ownership, that is impossible, because none of the powers involved in the attempt at conveyance could have had any part in the production of said land, and, therefore, could have no right or authority to transfer it, from the fact of an entire lack of title to transfer.

It may be objected that these are merely technical assumptions which the customs of society have never admitted. So, too, may it be objected to all encroachments of scientific principles upon old forms and customs. Nevertheless, science continues to analyze and demonstrate, and the world continues to come more and more under its guidance every year. In the principles of government science has not, until very recently, found grounds of attack. Since it has come to be recognized that there really is a science of society, and consequently that all its structure can be analyzed, understood and guided by its deductions many of the customs and practices that have so long controlled the people are found to be entirely without the support of principles fundamentally necessary to assure a permanently constructive form of society.

Wherever maxims of temporary policy are the guiding rules, there will ever be alternate construction and destruction; but wherever scientific, demonstrable principles are the governing power, there will be found permanency. That “money” is susceptible of analysis, and of being predicated upon a scientific basis is no longer to be questioned. It is a branch of the science of society, and as such must receive consideration as the science itself becomes disseminated among the peoples. It was not many years ago that “the sciences” were unknown in our common schools. It will not be many years hence until the science of society will be a recognized branch of every child’s education in the most enlightened portions of the world. Political economy, which is a branch of social science, is regarded with favor by many now, and, comprehensively speaking, all these questions which have been looked upon as “too abstract” for common comprehension, are found to be the real principles which underlie all social strictures.

First in importance, because it leads to the recognition of the “ultimate condition,” is the question of intercourse between the peoples of the earth. Money, as the means of bringing about this intercourse, should receive primary consideration. Let the fact once be generally recognized that the world is at last tending to “a unity of the peoples,” and financial and commercial unity are the introductory unities upon which to hasten governmental unity. Were these fully established upon a basis of mutual interest instead of upon the policy of each obtaining all the personal and selfish advantages possible, there could no such strifes as the one convulsing Europe to-day ever occur. Thus it appears that the assimilation of the world under one common interest is in the first instance a question of a unity of material interests which must serve as the foundation for all others to build upon.

Finance and commerce, then, lie at the very threshold of all the progress that is to be made in the direction of governmental consolidation, and when so recognized they will be rescued from the position that they now occupy as the means only of pursuing selfish interests, and be raised into that of principles and rules of action by which all intercourse must be regulated. Commerce, in its most comprehensive sense, does not apply merely to the exchange of the material products of the world, but to the exchange of intellectual, moral, social and religious products also, and its application thereby becomes common to all the interests of humanity. And as finance grows out of the necessities of commerce, it also becomes equally with commerce a humanitarian question. It is in this broad and general sense that all questions regarding it should hereafter be considered and not upon the basis of how much advantage such a measure will give an individual or a nation over another individual or nation.

Like all other questions that are now coming prominently before the world for solution, this one of finance and commerce rises to the dignity of a question of humanity. They are all to be considered in regard to their application, not merely to nations, but to all nations—all peoples—as forming the basis of the future confederation of the world under one government to be known as the United States of the World, when all the people will be inspired with a common Religious sentiment in regard to their primary origin and their ultimate destiny; when all the peoples will be governed in their relation to each other by the common social sentiment arising from the recognition of the fact that they are necessarily a community of brothers from having a common origin and destiny; when all the peoples will give a common adhesion to and support the deductions of a Universal Science, let those deductions militate as they will and must against whatever of speculation and theory there may still hang like a pall of night over the intellect of

man. To all of these ultimate conditions of mankind, finance and commerce must furnish the means of attainment; and being thus the first essentials to the beginning of the actual constructive process which, when completed, will be this grand consummation, they should be treated with that gravity and consideration which is due to so grand a position as they are assigned in the third order of general civilization. Policy should be entirely discarded from all place in the argument, and principles should alone be discussed. When the consideration is fairly begun upon this basis, scientific ideas regarding money will be rapidly diffused among the people, who now do not even dream that money can be reduced to the rules of scientific demonstration.

We urge again that this question should receive its proper share of attention at the hands of our next Congress as being the questions upon which the future good of mankind depends more immediately than any other that will be likely to command the undivided attention of it. This once settled upon the true principles, all other questions which all future Congresses will have to consider will be virtually determined by it.

NEW YORK, Nov. 4, 1870.

PAPERS ON FINANCE AND COMMERCE.

NO. XII.

In the treatment of these subjects in the general sense in which they become important to all the people the range is very much extended beyond that commonly compassed by those whose interest compels them to temporary considerations for the promoting of immediate interests under the systems in vogue. All such kind of treatment deals with effects, and would never remedy an existing want, nor correct illegitimate practices. If there are wants in existing systems, and if there are illegitimate practices which are possible under them, there is but one way to supply the one or to correct the other, and that is to go to the root of the matter where the causes exist which make these possible.

In this series of articles it has been the endeavor to point out some of the most prominent evidences that our financial system was unsound, and also to show, by as strict an analysis as was possible in the space allotted, what the true basis for a sound financial system was, and where it was to be found, and, having done this, such methods of administration were hinted at as would reduce the system, when put into operation, to a permanent and fixed measure of all values, which it was argued was equally as necessary when value is to be measured as the same fixedness is when any other quantity is to be measured.

It has been suggested by some that, in presenting our statements in the terse, undiluted manner we have, that those who have not been habitual thinkers upon this subject might fail to catch the full application of the propositions, and by so failing consider the system impracticable. To obviate such objections we shall, by further treatment of obscure points, attempt to make them plain to all who can understand the English language.

First, a brief re-statement and condensation of the entire outline: Money, being an invention to facilitate the exchanges of the products of labor, it should be formulated with direct reference to the conditions which made the invention necessary, out of which it should naturally grow; and also with direct regard as to how the invention should best meet the required case—that is, the invention should be adapted to the conditions, instead of making an invention without regard to the conditions, and then attempting to force the conditions to comply with the capacity of the invention.

This is a point which should be thoroughly comprehended, for in it lies the whole fault of making gold a measure of value, and we therefore shall attempt to offer a common illustration directly in point.

Let it be supposed that there is a stream which, to accommodate travel, requires to be bridged, and that the bridge has to be constructed and moved to the stream. The first procedure would be to determine just how long the bridge must be to span the stream. It would then be constructed and moved to the stream, which it of course would span. But suppose persons knowing there was a stream to be crossed, but not knowing its breadth, had gone to work and constructed the bridge and then had attempted to compel it, when too short, to extend across the stream. This would have been a case of attempting to compel the conditions for which the invention was made to accommodate themselves to the invention. And this has been just what the world has been all this time doing in attempting to compel the conditions for which money was invented to accommodate themselves to the possibilities of gold, which was invented as money without any reference being had to the functions it was to perform, or to the conditions it was required to meet.

It would be just as reasonable and just as sensible to attempt to compel a house to perform the functions of a bridge as it is to attempt to compel gold to perform the functions of money, for gold is not nor cannot ever be made to meet the requirements for which money is demanded; whereas, money should be of such character as to fully meet the requirements for which it is used, but should not be possessed of _any qualities that would render it useful for any other purpose whatever_, so that there could be no possibility of its ever being used for any other purposes, which impossibility would forever make speculation impossible.

It is believed that we have made clear the purposes for which money is required and also clear that it is utterly futile to attempt to compel any invention to meet those requirements where it is not formulated for the express purpose. We have heretofore shown that gold is a purely arbitrary standard which has no scientific relations whatever to the product of labor which it is required to measure, but that it is itself a product, and as such requires to be measured. A gallon of molasses would never be thought of as a measure of distance, but it would be just as reasonable to expect it to measure it as it is to expect a certain quantity of gold to measure the value of a horse. A horse may be exchanged for a certain amount of gold. So, too, may a horse be exchanged for a certain amount of wheat, but that process does not make either the horse or the wheat money. Money is that which can equally represent the wheat, the horse and the gold; and anything that cannot do this is not money.

Hence it is seen that every step we take in examining the true bearings of the money question brings us nearer and clearer to the proposition already made—that the capacity for production is the true basis of value.

NEW YORK, Nov. 11, 1870

PAPERS ON FINANCE AND COMMERCE.

NO. XIII.

We are perfectly aware of the very many objections which arise in the minds of the people to such a currency as has been proposed, but the thoughtless one of “What! an irredeemable paper money! Oh, no! that will never do; that means utter repudiation,” which is the most commonly made, scarcely merits attention. Will those, who so earnestly place themselves in opposition to a convertible currency, stop and consider for just one moment. What is the ten-dollar gold piece you have just received for a ten-dollar note good for? Will it feed or clothe you? or will it _directly_ minister to any of your needs or to those of any of your family? Directly, it will do none of these things for you; _but you can have it really redeemed by something that will_ feed, clothe and minister to all your requirements. You will thus perceive that you have been and still are laboring under a foolish delusion regarding this precious metal, for you have all the time been getting your paper money redeemed by your gold money, which you finally are obliged to redeem by that which is really valuable—that which it takes to maintain life and make it desirable.

Now, you know very well that the gold there is in the world cannot redeem or represent the values of the world. Were it a thousand times as valuable as it really is—that is to say, could the consent of the world be obtained to making the amount of gold which now represents one dollar to represent a thousand dollars—there would be a possibility of the gold in existence representing the value of the world; but as no such result as this is anticipated, it is in vain for you to cling to any such mythological and speculative theory.

Again: What terrible outrage would your conscience sustain if you would give a little calmer consideration to a proposition which you have always heretofore rejected without thought. With your gold you have been able to obtain that which you required to sustain and make life agreeable. These necessities, then, are the really valuable things of the world. What objection, then, can you make that can have the sanction, even of your own reason, to at once admitting that these are the only real values the world contains, and consequently—because legitimately—that whatever is money must be a representative of these valuables: and also and further, that anything bearing the name of money, which does not justly and fully represent the sum total of these, is not money in the true sense of that term.

Again: Money may be considered the negative pole of the battery of value. To all things there are two extremes and a mean, the evidence of perfection being that there is always an equilibrium sustained between the extremes through the medium of the mean. Products are positive existences which go forth to administer to the demands of human nature, and expend themselves in the negative returning force, money; which, in being brought back to the point which it represents, becomes a positive power itself, having the capacity to obtain labor which restores what has been expended, and thus the circuit is complete and nothing is lost; the same products exist and the same representation of them also exists. If, perchance the return of the products is not always immediately made, the power to return them is never lost, though that may be in a thousand years.

Thus it will be seen by all, if they will but give the necessary attention, that the proposed currency which shall be representative of the products of labor is not only the only natural money there can be, but that it can never appreciate nor depreciate, because every twelve months it is worth just one twenty-fifth part of itself—for it is believed that this per cent. of increase is the true balance between accumulation and production; if, on trial, this balance should be found too small, or too much in favor of production, it would be increased; and if found too large, or too much in favor of accumulation it could be reduced. This must be a subject of test, and when tested, legislation can increase or decrease the standard of value by making the “measure” larger or smaller, just the same as it does other “measures.”

We believe that the inauguration of such a money system would be the beginning of the “leveling down and the leveling up” of the capitalist and the laborer, and that such a thing as practical equality will be impossible under any less radical and comprehensive change from present systems. It is to be hoped that that large proportion of the whole people which is represented by the classes that desire to be “levelled up,” will give this most serious matter their most serious attention. We are aware that it is a subject but little understood, and that the prejudice of the people is in favor of the money god, gold. But, as in religion, so will it be in money; when reason and common sense are admitted to the debate, mythologic spectres and theoretic fancies will begin to assume their true shapes, and the realities to arise from the depths in which they have been confined.

NEW YORK, Nov. 25, 1870.

BASIS OF PHYSICAL LIFE.

THE UNITY OF LIFE, POWER AND MOTION.

I beg to present the following as the foundation for a series of articles which it is proposed to present in due time. At first glance it may be deemed too abstract for the purpose in view, but it must be remembered that all action is primarily derived from a common basis of life, and that it is from this basis all action _must_ spring, because general principles only are deducible from it:

“In the beginning was the Word, and the Word was with God, and the Word was God.” Although human conception cannot trace existence back to the time when “the Word was God,” the proposition is one which consciousness can accept without analysis, and define and understand as the Absolute in its broadest sense; but, when invested with the infinitude of phenomena and facts, the mind loses itself and gives way beneath the universal evidence that life, power and motion form a unit. Accepting, then, this proposition, without attempting to solve it, a basis is found from which to reason, and which we could not have discovered by reasoning backward from effects. God was in the beginning: the beginning was God. Acknowledging this, the mind cannot conceive of aught else existing in the beginning. He was the Supreme Whole, the great Central Heart, from and by which all things were to come. This truth should be fully accepted, for from it can be shown that the facts of the present are the legitimate outgrowth of this complete Oneness.

All nations have had a god or gods, though no two of them have been identical. Nor has the conception of a god remained unchanged with any people for any great length of time. Were each person to define his idea of a god, there would be nearly as many different ideals as there are individuals in the nation, thus showing that all knowledge is relative or symbolic. As there can be but one god conceived of under our proposition, the question arises how so many can be held up before the Christian world, and each claimed to be “the only true god.” In the solution of this will be found the chief burden which ignorance and superstition use to load the mind with their absurdities. Freed from this burden, the mind would form a true conception of the unity in diversity of nature, and recognize God as infinite and eternal. It will be readily admitted that God is indestructible. So, too, is matter. Then we have from the beginning two indestructibles—or, at least, for the present, it must be assumed they are two—God and Nature, Spirit and Matter, or Power and Resistance. These embrace “the Whole,” from which nothing could have been taken away or added thereto. As God, therefore, was All in All at the beginning, so he must ever remain the same; and this is true also of Nature.

Reasoning thus from this basis it must be found that every power has its origin in the first power—God, the mainspring of all action. Life, then, may be said to be motion making itself manifest under the influence of power—to what? It may be difficult for the mind to accept so broad an application of this all-pervading power, but it confesses it without comprehending it whenever it declares that God is omnipotent and omnipresent. The world little thinks of the extent of such an assertion, for it breaks down all the Christian ideas of that antagonism known as the Powers of the Devil; it banishes the possibility of creation proving a partial failure and enables the soul to recognize an ever-present, all-pervading, though inscrutable God.

It may then be asked, Is God omnipotent? If believers in an incarnation of Evil answer yes, what becomes of the foundation for such a belief? If no, what becomes of their God? If He be omnipotent, He must be not only the source of all power, but All Power. To assert otherwise is to declare that there are two infinites—an assertion which contains its own refutation. While the mind can conceive that God is All in All, it cannot at the same time conceive that He is not All in All, or that the Devil is a part of the All in All, in opposition and contradistinction to God. Those, therefore, who believe that God is All in All, and also believe in a Devil, believe an impossibility, for two persons or things cannot be the same, or occupy the same place at the same time. The absurdity, then, of the divisibility of the Supreme Power becomes at once apparent. The argument is of importance as it furnishes a well-defined basis, which meets every difficulty and arrays it in support of the unity of all things and the supremacy of God.

The question, what and where is God? has been often asked; but the various attempts to answer the unanswerable, have only given the unreflecting mind another's idea instead of a just and comprehensive conception of God's complete existence. In reasoning on so important an inquiry, the mind should soar above principles and ideas, and in one vast grasp say that God is the whole. Where is God? He is everywhere. In this answer we have no clearer solution of the query than we have when we say God is incomprehensible to the human mind; still the form is such as the mind can use in measuring its relative parts.

From the Great First Cause, and from it alone, has come the present in all its beauty and variety, material and spiritual. Though the effects may continue to increase in number throughout an infinite future, the sum of them can never amount to the First Cause. God must and will forever remain superior to all the effects of the workings of this power.

The material universe, science tells us, is composed of some sixty-four or more elementary parts. An element cannot be resolved into two or more different substances. These elements combine under certain conditions and in certain proportions with each other to form compounds differing materially from their component parts. Everything we see in nature is formed of these elementary materials; yet, extensive as these compounds are, they are fashioned according to universal and unchangeable laws. While the existence of any of the elements uncombined is rare, their combinations fill all space, and are co-extensive with the Divine Spirit. Spirit and Matter—God and Nature, seem, therefore, to be forever united.

But how have all these things come? What is this inexhaustible power everywhere manifested, and what the laws governing its application? Go back to the time when no compound bodies existed on this planet, and what was there? God was there in all his absoluteness, all his infinity. All the elements of matter were there in the same proportions and quantities as now exist, but uncombined. In an abstract sense, an element is a unit mass, without life, power or motion. What constitutes it an existence, gives it life, power and motion, and the capacity of combining with other diverse existences? We cannot conceive of matter, even in its simplest form, as devoid of all active life principles, for that would be to conceive a place, occupied by matter, where God is not. Each element, therefore, contains its portion of the Eternal Spirit, without which it would not even be a substance, but with which it can unite with other similarly endowed simples. It seems impossible not to conclude, then, that the life, power and motion found in all material substances, is that life and power we call Infinite.

To further illustrate this indwelling life principle, we quote from a celebrated author, who, speaking of the "winds and currents of the sea," says: "Men try to explain everything by the wind and the current. Now there is in the air a force which is not wind, and in the water a force that is not current. This force, the same in the air as in the water, is effluvium. The air and the water are two masses of liquid nearly identical and changing mutually into each other. * * * The effluvium is alone fluid; the wind and the current are only impulses. The effluvium is a steady stream * * * and is invisible. Yet from time to time it says, 'There I am;' and its way of saying so is a thunder clap. The sea is as much magnetic as watery. An ocean of forces floats unknown in the ocean of currents. To see in the ocean only a mass of water is not to see it at all." To which we would add, that to see in the manifestations of nature, nature only, is not to see it at all, for the power producing it is not recognized. What is seen is not the reality, but that through which the reality makes itself known.

What has thus far been considered may be consolidated into this comprehensive proposition: That there is a power existing everywhere, of which we can know nothing absolutely except that consciousness tells us it is. At the same time we are conscious of our incapability to define or comprehend it, and that all we can ever know of this power is its physical manifestations. Hence the knowledge of what we see, hear, feel, taste and smell is abstractly symbolic and relative, the only absolute knowledge we can possibly have—if knowledge it be—is a consciousness of our infinite existence. In this view of the existence of God, which is the basis of all religious ideas, religion may be said to be superior to science, because it remains immovable in consciousness. Religion belongs to the unknowable; science deals with the knowable, which is the manifestation of the unknowable. Therefore, viewed philosophically, religion and science stand for the subjective and objective whose relations comprise the whole. The presence,

then, in consciousness, of what we can by no means account for, must be the actual presence of that of which consciousness is made up—the elementary spiritual principles representative in us as individual existences of the great Infinite existence.

Ambiguity in the use of terms leads to confusion of ideas and thought, and is one great general cause of the ignorance and superstition still existing among apparently enlightened nations. Many terms, supposed to convey certain well-defined ideas, are found to be deficient when analyzed, and others stand for nothing in substance. Many are in common use whose meaning the man of religion, science or philosophy would be embarrassed to explain. Chief among these are: The Infinite, The Absolute, Causation and Effect, Power, Motion, Matter, Space, Time, Resistance, Eternity, Immortality, Good, Evil, Heat, Light, Rewards, Punishment, Justice, Law, Order. As the argument proceeds it will be seen how nearly the whole of these and many similar terms are resolvable into the few which convey realities.

All things that can be resolved into parts cannot be said to be existences. Existence carries with it the idea of permanent continuity, something self-dependent, superior to everything else as an entity. What one term will express absolute superiority? The universe of space is occupied by matter which, acted upon by an incomprehensible Power, produces manifestations or motions. These being successive, time becomes a necessary constituent. Do we need any other term to cover all the manifestations? Is there any part of the universe left untouched by the few terms? But allowing that they include the Whole, some one must be of primary consequence, while the others are auxiliary thereto.

The term Motion will be found, on analysis, to be the result of Power acting upon Matter, and the proposition is comprehensive enough to include every known movement. Hence every manifestation in the material world can readily be accounted for by the combination of these two terms. Though not so immediately apparent, it will be shown that mental manifestations are also included in this. If all manifestations are then explainable by these two terms, all minor terms must be but names for the different forms under which these two manifest themselves, and into which they must ultimately be resolved. Motion, it was found, was resolvable into Power and Matter. Can these be resolved into anything more general than themselves?

The universe is composed objectively of matter. Is it made up of anything else? An absolute vacuum is an impossibility in thought. Then what we term space is filled with something, and only matter is comprehensive enough to include all. But matter alone would convey the idea of space filled with something at perfect rest. The term motion then becomes necessary. This involves a subject, the cause of the motion; and an object, the thing moved—power the cause, motion the object. Can these be resolved into anything more general? As stated, the universe is composed of matter, manifesting itself by and through motion; and motion, as was seen, can be caused only by the application of power to matter, and no other term is sufficiently general to comprehend the causes of motion. By the union or duality of power and matter everything is brought within the sphere of consciousness, if not of comprehension. But which of all the manifestations of power acting upon matter is of primary importance? Of which does consciousness earliest take cognizance?

The universe of matter is boundless. Space conveys the idea of something beyond which there is nothing. Else it would be limited by that which is beyond, and we can conceive of nothing as existing without extension, and extension implies the occupancy of a certain defined limit, which limit must be within space. Space being undefinable, that which occupies it must partake of the same characteristic when considered as a whole. The same line of reasoning applies to power and time. Succession of events compels an occupation of a part of infinite duration as matter, relatively considered, occupies space; that is, between two or more separate facts there must be a lapse of time before consciousness can arrange them so as as to take cognizance thereof. Whether this is of itself an actual existence, or some method of an actual existence, it is a necessity to consciousness. Hence, time is related to power as space is to matter. Power and matter being the subjective realities, while space and time are their objective results, or the necessary effects of the experience in consciousness of their united result, which is motion. Our ideas of space and time are derived from experiences of power acting upon matter, while motion, the effect thereof, unites the two in consciousness as relative realities which must be a part of absolute realities.

It is clear, then, that all we can know of the unknowable arises from our experience of power and matter, and that within the sphere of their manifestations all effects are included. But while each is necessary to produce effect, we must not forget that we would have no consciousness of the existence of matter were it not the object of the application of power; hence we must conclude that power is of primordial importance, and, as such, the most general and comprehensive of scientific terms. All knowledge and consciousness grow out of experiences of power, which must be considered the general ultimate. All theories regarding it are but theories. Power is untouched by them, while matter, space, time and motion may be considered either as its constituents or as modes of its manifestations.

To make the argument more complete to those unaccustomed to resolve phenomenon into its ultimate cause, some illustrations of such resolutions will prepare the mind to accept the conclusions arrived at: Let it be supposed that some circumstance calls for the manufacture of cotton cloth unlike, in some respect, any ever manufactured—say in width—how must it be produced? Reasoning inductively and given the raw material, the last necessity apparently is a loom that will admit of the width required and the prepared webbing and filling. Still, the cloth cannot be produced without the further aid of motion in the loom, which motion must be generated by power through certain machinery, obtained from setting free such portion of power as had been concentrated in coal. This expands water into steam; steam in escaping compels the piston of the engine to move, and this motion is communicated to the loom, the required cloth being the effect. It will be seen that whatever intermediate processes were necessary they were all resolvable into the power concentrated in the coal. What was then of first importance in the production of cloth? It was neither the loom nor the cotton nor the machinery, but the power giving motion to all. This illustration may be used symbolically to explain everything incomprehensible in the universe, that is, all manifestations of power working in and through matter, producing motion and its effects.

All material effects being explained by power acting on matter, may not this simple formula equally symbolize all mental operations the product of which is thought? The question primarily arising would be, what is thought and how is it produced? Let us analyze it. Something cannot be produced from nothing. Thought is something. Thought is then the product of something previously existing. Immateriality cannot be conceived of. Therefore thought is not only material in itself, but the product of matter in motion; and as motion is only possible through power applied to matter, thought must be a result of such an operation. Can it be explained and comprehended upon this theory? Let it be supposed that some great noise should suddenly occur just outside a house in which were 5,000 people. Each one would ask the mental question, or “think,” What was that caused by? Now, that thought would be the product of the sound heard. But how heard? Simply thus: Rapid vibrations of the air, caused by some unknown matter in motion, came in contact with the organs of hearing, were transmitted to the nerves, and finally taken up into consciousness. The whole operation is a purely physical one, and there is a perfect equivalent between the amount of vibration and the resulting sensation; in other words, the effect corresponds to the cause. It may also be remarked that a hundred physical bodies of different weights produce as many different sensations; the difference being always in exact proportion to the difference in their respective weights. Similar differences follow when matter at various degrees of temperature comes in contact with the body. The same is true regarding light upon the optic nerve.

Let us next see if that variety of thought or sensation which arises spontaneously within the individual is due to any different agency. Perhaps the most comprehensive and conclusive evidence of the material origin of thought is, that a child born under even favorable circumstances, but kept from all external, material and mental manifestations, grows up a simple idiot. Without, then, the manifestation of power acting upon matter, no original individual thought or conception is possible with the supposed exception of spontaneous thought hereafter to be treated. Further evidence of this is seen when an adult is kept in solitary confinement, or cast away upon an uninhabited island; memory fails, language is lost, and the person becomes a semi-idiot. The following extract, from an address by Dr. J. W. Draper, is made to show that scientific men are admitting the fact that the mind is the result of the processes here indicated—a collection of facts gained by impressions constantly repeated. He says: “There are successive phases * * * in the early action of the mind. As soon as the senses are in working order * * * a process of collecting facts is commenced. These are at first of the most homely kind, but the sphere from which they are gathered is extended by degrees. We may, therefore, consider that this collecting of facts is the earliest indication of the action of the brain, and it is an operation which, with more or less activity, continues through life. * * * Soon a second characteristic appears. The learning of the relationship of the facts thus acquired to one another. * * * This stage has been sometimes spoken of as the dawn of the reasoning faculty. A third characteristic of almost contemporaneous appearance may be remarked—it is the putting to use facts that have been acquired and the relationships that have been determined. * * * Now this triple natural process * * * must be the basis of any right system of instruction. It appears, then, that contact and constant intercourse with external manifestations is not only necessary for the production of thought and its collaterals, but that to retain the consciousness which makes thought possible such manifestations must be continuously impressed upon the individual. This seems to be conclusive that mind is the result of the experiences of the manifestations of power.”

There is still more subtle evidence that thought, which is only the memory of past manifestations of power, or deduction of reason upon them, is the product of material action. All mental action depends upon the nervous apparatus, and is limited by its capacity. The activity and power of this apparatus is in a great measure dependent upon the quantity of phosphorus supplied to it, and this varies at different periods of life.

The point in question is further sustained by the fact that the rapidity of thought varies with the supply of blood to the brain. Reduce the action of the heart to forty beats per minute, and a feeling of languor permeates the whole system. On the other hand, excess of cerebral circulation results in excitement amounting sometimes to actual delirium. We must, then, either admit that mental action is a product of material power, and consequently itself material, or else conclude that, while it is the result of the expenditure of power, it is in its character immaterial, which would be absurd, because it is impossible to represent immateriality in thought, as consciousness requires a subjective action and objective reception of it to complete a thought, while immateriality is neither.

Not only is mental action affected by the quantity of blood supplied to the brain, but also by its quality. This is fully shown in the progress of certain diseases that prevent its being properly oxygenized, and even more conspicuously in the administration of anæsthetics. A similar effect can be produced upon the brain by deep, full and continuously rapid breathing, by which an undue amount of oxygen is introduced into the circulation.

It appears, then, that having a perfect nervous apparatus, certain special materials must be supplied to it from or by which to manufacture mental and nervous action. Excessive mental action and powerful and continuous emotions produce, as everybody knows, physical prostration. From whatever position, then, we may view any action the physical, mental or nervous system is capable of producing, we come finally to the conclusion that they are possible only as the result of the expenditure of some physical power, and every mind that will justly consider the evidence must give its adhesion to what science is rapidly making plain.

Before closing the consideration of thought another phase of its manifestations demands attention. Who has not observed the effect of one or two minds concentrated upon another person unconscious of the intention? The object of such concentration becomes conscious of the fact, and invariably, though involuntarily, looks in the direction whence the influence proceeds. Before following this to its legitimate deductions it must be taken for granted that there is an individual existence after the dissolution of the physical body. Nearly all people accept this as a part of consciousness. From two propositions already received and well understood, a third may be deduced, and along with it will follow such legitimate additional thoughts, ideas, impressions, and modifications of former ones, as such deductions necessarily imply. But how shall those thoughts not derived from anything already in consciousness, be accounted for? And are not all conscious of receiving many such thoughts in passive conditions and during sleep? Following up the truth that something cannot be produced from nothing, the source of these must be found, else our premises are false or incomplete.

Every variety of mental action can be communicated. Given a mind possessed of a new truth and one that has not yet perceived it, the former can communicate it to the latter. This communication and reception have been effected through the medium of speech. Another method is through written or printed language. All this is simply symbolic. Sounds and written or printed forms are in themselves nothing but motion in the atmosphere and material formations by common consent accepted to represent other and previous material formations. The one thing of primary importance is, that the symbols used must be previously understood by both parties to represent identical things at all times. Thought, expressed in an unknown language, is not comprehended; this indicates that thought abstracted from form is never communicated. It cannot rise into consciousness even, except through an established form. Capability of thought is only possible as the result of constant contact with external manifestations, systematized under certain regular and received forms which always remain purely symbolic.

It remains to be considered how mind affects mind, through the concentration of the will, without the apparent use of the above methods of communication. We have seen that sounds produce an effect upon the object through the sense of hearing. But can you analyze hearing, and show how the sounds rise into consciousness? When forms are used an effect is produced through vision. But how does vision rise into consciousness? We have seen that an effect is produced by a concentration of the mind upon an object, but how this effect rises into consciousness is beyond our comprehension.

We can now proceed to the application of what has been offered, to the communication between minds by other methods than sound and form. Whence all these thoughts and impressions that steal into consciousness through no apparent form? The conclusion seems inevitable that mind can influence mind, whether it be within a physical organization or out of it. We predicate, therefore, that all thoughts, ideas, impressions, and sensations not coming from present external manifestations nor from previously acquired facts, nor yet from direct communications through recognized symbols, are emanations received from some unknown mind either in or out of the physical form. Nor can we escape from this conclusion, unless we concede that this case forms an exception to the general law. All forms, then, of thought, emotion and sensation are the legitimate result of the expenditure of power, and may be arrayed in support of the premises that Life, Power, and Motion, wherever found, are Unitary.

Let us consider in continuation, what application this unity has as the basis of physical life. What constitutes this basis? Is physical life the direct effect of the edict of a God reigning over the whole universe from some unknown point within it? No, the theory of a special Providence is fast giving place to new and better things—to law and order. It is beginning to dawn upon mankind that “the only true God” must be beyond our comprehension as the universe is, and that it is folly or presumptive egotism to assert that God is this or that. A God possessing such inconsistent infinite powers as are usually ascribed to him, is fast being discarded by all thinkers. Therefore the basis must be sought elsewhere.

The universe is ruled in uniform ways. Special enactments for special contingencies are inconsistent with our conception of the nature of that general law by which all is governed. This alone is inferable, when viewed with the conclusions previously arrived at, that things of which we can be conscious are unitary in origin and in ultimate effect. Supreme rule is removed beyond the pale of vicissitudes of time and circumstance. The deduction, then, is that the cause of physical life is universally the same, the manifestations being varied according to the properties involved in them. Does life then consist of anything more than this uniform Basis Power?

The world of mind demands facts, not theories. Truth is no longer feared, no matter how terribly it may shock the sensibilities of the religiously-educated and philosophically-dwarfed intellect. Let us have truth, then, even if it strips away the last of our preconceived opinions. The cry for more light continues to extend. You who cannot yet endure its brightness hide yourselves behind clouded dogmas, creeds and theories. We know no creed but that which declares that an infinite, inscrutable Power is the life of all things, material and spiritual; we know no dogma save that life is the operation of this Power; we know no theory but that which makes clear the laws and modes by which these operations are governed.

Discarding, then, all dogmas, the growing minds strikes boldly out for truth, and he who catches but faint glimpses of it badly performs his duty if he attempts to hide it from his brothers. If in its attainment the Church crumbles, why falter? If governments totter, why falter? Whatever will be crushed out by new discoveries and publication of truth has already performed its mission. Suppose, for example, that the grossest materialism ever conceived of was absolutely true, would it not be best that the world should be convinced of its truth? It speaks little for any system of religion or philosophy that it cannot bear the light of facts, but evades, shuts out, or hurls anathemas at that which it cannot refute. Such a course stands condemned before the tribunal of a progressive philosophy. The very effort of a late institution in opposition to physical freedom precipitated upon it its own destruction; such will doubtless be the result of an attempt now being made by a powerful institution to rivet religious bondage upon its subjects.

In continuing this subject, extracts will be made from Prof. Huxley’s lecture, “The New Theory of Life, or Matter the Basis of Vitality,” to show that science has demonstrated that “life” is the same everywhere; and though he disclaims materialistic philosophy, the tendency of these extracts is in that direction. While matter must be looked to for all expression of facts, it must not be overlooked that the realm of power or spirituality is the producing cause; consequently, while allowing science full scope in analyzing, demonstrating and systematizing facts, religion must not be despoiled of its basis idea which remains immovably fixed in consciousness. The Professor says: “I have translated the term _Protoplasm_, which is the scientific name of the substance I am about to speak of by the words ‘The Physical Basis of Life.’ * * * * To many, the idea that there is such a thing as a physical basis or matter of life may be novel. * * * Even those who are aware that matter and life are inseparably connected may not be prepared for the conclusion plainly suggested by the phrase ‘The Physical Basis of Life.’” After giving various illustrations, drawn from nearly every department of nature, grasping contrasts and dissimilarities, he adds: “I propose to demonstrate that, notwithstanding these apparent difficulties, a three-fold unity—a unity of power or faculty, a unity of form and a unity of substantial composition, does pervade the whole living world; * * that the complicated and multifarious activities of man are comprehensible under three categories—either they are immediately directed toward the maintenance and development of the body, or they are to effect transitory changes in the relative positions of parts of the body; or they tend toward the continuance of the species. Even the manifestation of intellect, of feeling and of will, are not excluded from the classification.”

Prof. Huxley then illustrates the action of the _protoplasm_ in the common nettle and in the drop of blood, showing that both plants and animals have their origin in a particle of nucleated _protoplasm_, and that this _protoplasm_ “not only dies and is resolved into its mineral and lifeless constituents, but is always dying, and strange as the paradox may seem, could not live unless it died.” Thus we are led to the conclusion that all matter has a common basic principle by which we obtain our evidences of it. It is equally clear that analysis fails to grapple this principle, for the process dissipates the power that compelled the combination. Dead _protoplasm_ differs from living in that something has departed from it, and though we cannot catch this to decide upon its nature, can we with consistency say it is a property of matter? If it is, what has become of it that it does not manifest itself again upon the recombination of the matter it once made use of? One fact is evident, and seems to be conclusive. This life principle never

manifests itself through artificial combinations of matter. Again, is there no difference between ordinary matter and “matter of life?” What changes the former into the latter, and _vice versa_? If chemical analysis can tell us nothing about the composition of living matter, what can it tell us of life itself? If nucleated _protoplasm_ is the basis of all life, and yet nothing but matter, why does one “structural unit” of it produce a plant, another an animal? While it is evident that the material composition of these units is uniform, it seems to be quite absurd to say that chemical analysis teaches everything that they comprehend.

If the manifestations of matter are the result of its properties, the law must be of general application. Water always seeks its level: is that a property of water or the result of gravitation? Water can be expanded into vapor: is this a property of water or the result of the introduction of heat? Is it a property of matter that transfers the digestible and animal food we eat into man? Does man exhibit nothing but the properties of matter? It is evident that after the strictest chemical analysis the vital life principle common to all matter remains unreached—thus indicating its great ultimate character, which is beyond the reach of both chemical and mental analysis.

What is this power by which the nucleated _protoplasm_ of the various species always produces representatives of the one which furnished the germ? If it were simply a property of nucleated _protoplasm_, considered as matter, why should not a germ from the lion just as readily produce a lamb? In the various crosses between animals, the aggregated masses of _protoplasm_ partaking of both, the inference plainly is that in each of the particles of _protoplasm_ was contained a power which controlled their successive aggregations and modifications. Other evidence that the determining power is something more than a mere property of matter is found in the fact that if the young of several different species of animals be reared in company and fed with the same material, they will each retain the peculiarities of the species they represent, modified somewhat by the community of influence exerted on them. The same is true of the offspring of different races and nations.

The law indicated is still more generally applicable, descending as it does from the wide range of species and nations to each individual member thereof. Upon different individuals the same cause, acting under like circumstances, produces different effects, and this difference is dependent upon something more persistent than matter which is constantly changing. Is this persistent individuality a property of the matter we possess now, or of that which we shall be made up of some years hence? The consciousness of each one answers that this individuality is superior to the vicissitudes of matter—this consciousness having this peculiarity over its consciousness of the manifestations of matter, that while it constantly acquires new experiences it loses none of those previously acquired.

We know nothing of this power, except that it is a name for an unknown cause: and so far as practical utility is concerned, the distinction between power and matter might be discarded, the danger of falling thereby into the slough of materialistic philosophy being avoided, if we remember that all the knowledge we can acquire is simply relative and symbolic.

Returning for a moment to the fact of reproduction, to ascertain if possible the determining power by which one “structural unit” of nucleated protoplasm develops into a beast, and another chemically identical into a man, and realizing fully that this power is beyond common modes of proof we infer that a reasonable conclusion can only be deduced from observing the general unchanging law of the constant recurrence of similar results under similar circumstances. The first step in the inquiry is to ask what “protoplasm” is, and how and where it is obtained.

Prof. Huxley informs us that its chemical constituents are carbon, hydrogen, nitrogen and oxygen, which form carbonic acid, water and ammonia; and that these are compounded by plants into the “matter of life” or protoplasm, which is the first compound of elements possessing inherent organic motion. This being the only way protoplasm can be produced, we must always look to the vegetable world for continuous supplies of it; and though we obtain it in large quantities from the animal world, it is only at second-hand. In the vegetable world, then, must we find the first traces of organic life. But though plants thus manufacture protoplasm, they are not wholly protoplasm, but consist of various other elements necessary in an organized form. The manufacture of protoplasm may be considered the end of the vegetable world. This substance builds up the animal world, and forms a connecting link between the kingdoms.

How long it took protoplasm to produce its ultimate animal man we cannot ascertain, but the numerous species and varieties thereof between the simplest and most complete compounds signify a labor of which we can scarcely conceive, and yet science has traced and classified it all, each succeeding link in the chain being a little more complex, until man appears. As no higher types have been produced it is fair to presume that none can be. The formula, then, that will present man will include everything below him in the order of creation, not only in the animal and vegetable kingdoms, but in the inorganic world upon which the vegetable is founded.

It remains to be observed that in the order of nature each of the various species of animals reproduces its kind, and gradually merges into the next higher, but never recedes. Each species represents in different proportions and numbers the “structural units,” from which, reproduction follows, each unit containing the life principle representative of the general life principle of the animal from which it comes. Now, it is predicated as a result of the study of nature that this life principle is the determining power that controls the process whereby protoplasm builds up such various and dissimilar material reforms. Dead protoplasm consists of carbon, hydrogen, oxygen, and nitrogen; living protoplasm, of these permeated and held together by this life principle, and this differs in its controlling power according to the formations it has gone through. Thus the “structural unit” of the lion or of the horse, containing the life principle peculiar to each, develops into a lion or a horse, as the case may be, unless in this process it is furnished with living protoplasm containing a life principle of different determining powers, when the aggregate result is a modification of the two powers.

Again, if the phenomena presented by matter are its absolute properties, the same elements and combinations should always produce identical results when taken into the human system. Do facts coincide with this? This “matter of life” should, if it is simply matter, always produce similar effects from whatever source it is derived. It is a physiological fact, however, that habitual living upon certain kinds of food—all containing this identical “matter of life”—does produce heterogeneous effects, mental and physical, upon the system. Thus, if a person who has constantly lived upon animal food changes his diet entirely to fruit and vegetables, a corresponding change will take place in his individual capacities.

The same point is well illustrated by a case which occurred in England, where saltpetre, obtained direct from the soil, was quite inert compared with that obtained from animal substances, the cause of the difference being due to the tact that the latter, in passing through the animal kingdom, had acquired a power which it did not previously possess. This illustration is of general application. It is evident that matter, in passing through each successive and higher organic form, becomes impregnated with the life principle which determines such form, and which manifests itself in all future combinations into which such matter enters.

The question now naturally arises, Is there a life principle common to all matter, which has become variously modified as the elements of matter have become modified by having given rise to or passed through the different changes and steps between its original homogeneous state and its present heterogeneous condition? Or are we to conclude that all matter is dead, except that termed “matter of life?” That there is, consequently, no life except organic life, and that this organic life is a special creation entering into a single compound, which thereby raised to the dignity of “matter of life,” makes use of other elements as auxiliaries to its supreme rule? With all proper deference to “matter of life,” we would ask, what do we know of life except as a result of motion? and where can matter be found that does not manifest motion? and how could the compound in which the “matter of life” is first found, have been compounded without motion? If the life principle, manifested by protoplasm, is simply a property of matter, I see no logical reason why the motion existing in matter should not with equal propriety be called its property. This brings us to first principles, to the threshold of elemental combination, for if this power determines the forms compounds shall assume, why should it not determine simple elemental form also?

Protoplasm is the foundation of all organic life; and if we add to this that this substance is itself the ultimate of a previous system of formation, the formula will express the whole. Yet it must not be forgotten that the building up of organic life is the result of a constructive power common to the universe, and not indigenous to protoplasm alone. It must then be apparent that there is a power common to all matter, of which the motion or life inherent in living protoplasm is but a modification; also, that the capacity of this common power for modification is only limited by the necessary forms to represent it, and the time required to develop them.

If this view of the power that pervades the universe is correct, the real basis of life lies retrospectively far behind the motion contained in or manifested by the matter of life, and this motion, instead of being life of matter in its absolute sense, is but one of its modes of expression. This homogeneous power common to matter still exists, undisturbed in extent, though most heterogeneously distributed in the formations which make up the present external universe.

The basis of physical life, then, is this power, and this power is the same that was found to be unitary, though incomprehensible in its extent, while its manifestations are simply symbolic of that unlimited power which is alone attributable to the Unknowable, commonly designated God. If this conclusion is not in accordance with the modes of manifestation, there is no halting-place between it and the opposite extreme of the materialist that “there is no God”—that matter is all there is in the universe. If materialistic philosophy involve “grave error,” it becomes the duty of all who detect this tendency to preserve and point out the distinctions between the “matter of life” and the life of matter.

If the true province of philosophy is to discern the “soul of truth,” said to exist “in all erroneous things,” it ill becomes the ultra Spiritualist with a “soul of truth,” contained within his vast body of errors, to denounce the ultra Materialist, who, if he has not the “soul of truth,” has a vast body of it. To the superficial thinker, the Materialist may seem to be the more consistent of the two, as he can in part comprehend his truth, while the Spiritualist cannot. Whether one is more or less consistent than the other matters not, so far as their predications are concerned.

But the ultra Spiritualist would show his consistency by descending to the plane of the Materialist to find in his “body of truths” evidences of the handiwork of his God, which his ultra religious ideas fail to furnish; and the ultra Materialist would show his by ascending to the plane of the Spiritualist to find in his “soul of truth” the key that shall transform his “body of truth” into living evidence of an unlimited Power entirely beyond the pale of matter or the keenest scientific analysis.

TENDENCIES AND PROPHECIES OF THE PRESENT AGE.

[Revised from the American Workman of October 9, 1869.]

NO. I.

It is eminently proper, before approaching the future of any subject, to make strictest inquiry and most diligent search in and around its present—to look with retrospective glance upon the convergent paths of the past that have led to its present, and to catch the indices pointing onward; and, having found them, to judge whether such as Time’s unfolding calendar has left here and there along the pathway of passing events were reliable prophecies of what was to come—were truthful indications of what was to follow. In the judgment determined and warranted by the evidences obtained, a certain basis may be found upon which to predicate the prophecies of the living present.

The existing present is the absolute result of the eternal past; the sum total of all that has gone before; the product of God’s everlasting workings, by and through unchangeable law upon the elemental material universe; nor can there be extracted from this result, this sum total, this product, one simple separate effect which is not the legitimate offspring of the operation of immutable law, co-extensive with the universe, and co-existent with God.

A proposition that there are powers within God’s realm which did not spring from Him, or that the Original Cause has, in the economy of Nature, found it necessary to amend and change the original law, in order to accomplish His original purpose, or that contingencies have arisen which have demanded special enactments on the part of the Divine Ruler, presupposes that God did not know the end from the beginning, or, knowing it, was incompetent to provide therefor. Such a proposition, entertained by the human mind, destroys within it the God of the universe, and leaves the world, to it, a mere toy in the hands of its master, subject, at all times, to the caprices of his infinite rule, to be led here and there by circumstances he knew not of previous to their external development.

It may be said, that reasoning upon the character of God’s government, or the mode through which he manifests himself to the world, is not pertinent to the subject in view; to those who think thus the query should be propounded—What of the _future_ without a reliable present? and what of the effects that must follow, if the operating, existing general laws of the universe be not the same in a thousand years as now? It becomes, then, extremely important that some permanent, unchangeable basis be found before proceeding to predicate the future; and unless God is the same yesterday, to-day and forever, we can find no certain basis upon which to stand and from which we can start.

We have but to question the earth whether or not, from its incipiency onward through countless ages, it has obeyed the one great command, Progress? and in answer received, determine if, in the past, God has found it necessary to change the great fundamental laws of the universe. Geology tells in unmistakable writings what the earth was; we have but to look about us to see what it is. At no time since _it was_ can we learn that the law of progressive unfoldment has been inverted, and the world turned backward toward its commencing point. Since this has not occurred in the past, we may safely assume that it will not occur in the future; the law of progress may be accepted as one of God’s immutable decrees. The universe to-day, in all its variety and beauty, is no more in essence than it was millions of years ago, when it first assumed its orbital movements; the same elements exist in the exact quantity—nothing added—nothing taken away. Progress is simply a new arrangement of elementary principles.

Simple elements are indestructible; when two or more are combined, and produce an effect, the combination may be destroyed, and the elements separated and returned to their natural condition. This process is not one of destruction, but simply of change of

the relations of the elements that formed the combination. An acorn deposited in the earth attracts to itself such elements as produce growth; after years of labor, the mighty oak is the result. Although in its formation it has taken from the earth and air certain properties, the same quantity of such proportions still exists—nothing new has been created, a new form only has been produced by Nature, testifying that she never rests. Now, suppose a power were applied to the oak to dissolve it, the oak only would be destroyed, not the properties that entered into its composition.

It is supposed there are a certain number of elementary principles contained in and that make up the material universe; were these principles simple units, incapable of divisibility, we could, by applying the rule of geometrical progression, soon arrive at the exact number of different combinations, and consequently the exact number of different forms they are capable of producing; but, being infinite in quantity and divisibility, infinitude of form and effect is possible. The power of arrangement being infinite, infinitude of association and combination is the legitimate result.

Combination and association began in the simplest forms! When God, by his omnipotent voice, spoke the earth into existence, as an individual planet, it contained exactly the same elements of which it is now composed; but they were simply in elemental form, without organization, and, consequently, without variety of manifestation in form; motion being an inherent quality, constant agitation brought the elements into relations and combinations, simple at first; but by constant change they arose from the simple to the complex, and from the complex toward the infinite, and in the sum total of them we have the living present.

The argument does not require that minute examination of geological science be made, following, one by one, the rise and fall, the organization and destruction of each of its classified periods, nor of the specific results by and through each; but only to recognize _the law_ by which these results are arrived at. It is possible to so trace and classify these results as to show a continuous chain of progression, link by link, from the simplest form of combination, to the most complex and perfect, wherein all the original elements were first represented—man! Having arrived at perfection of form, wherein all the properties of the material world find themselves forming a part, it might reasonably be accepted that progression in formation would cease; while it has ceased so far as producing higher types is concerned, it has not in the quality of the types already produced; and in this proposition lies the greatest problem of life; the one most difficult for the human mind to grasp. Man, representing in form all that has gone before, is the result of the grand chain of progressive material formations; and, having combined within his physical form a portion of every element contained in the world, he may be likened in his infancy to the infancy of the earth. God, in spirit, pervades all material nature, and the union—if union it may be called—forms a perfect whole, and man being an epitome of all things contained in the material world, receives into his organization the spirit of each of its representative constituent parts, and consequently is endowed with all the spiritual attributes of the universe, the attributes of God! and, as God is eternal, man, created in His image, must likewise be eternal.

As the earth, in its first efforts at organization, combined but few of its principles, and presented the crudest form, and as time rolled on and its combinations continued to include more and more of the several principles, so with man; in his infancy his spiritual manifestations were crude in the extreme, but there has constantly been brought into co-operative combination, more and more of the spiritual principles, and higher and higher types of spiritual manifestations have been the result.

If man, as a unit, were analyzed to-day, he would be found to be made up spiritually of the elements corresponding to that age of the development of the physical world of which he is now the representative; that is to say, in his manifestations spiritually, he exhibits the same ratio of spiritual elements that the earth did in her manifestations in material elements at the time in her growth corresponding with the present condition and growth of man.

If cool and deliberate reason, unbiased by mythological and theoretical dogmas, be applied to the correspondence between the material and spiritual elements, the conclusion can scarcely fail to be arrived at, that each primary element of the material universe is the external expression and representative of a spiritual attribute of God; and as there are a definite number of elements in nature, forming the perfect _material whole_, so there are an equal number of analagous spiritual elements that constitute the _spiritual whole_.

As the elements and their corresponding interior principles are susceptible of infinite combinations and associations, the varied manifestations of nature and man are readily accounted for. Nor should it be forgotten that each of the manifestations is the legitimate and inevitable result of the combination out of which it springs; and, as the combination is not self-creative, but the result of the action of progressive law, so the effect of the combination is but the outward expression of the purposes contained within the law, behind the formation of the combination, and is thus the result of God’s operative law of progress.

Having argued thus far to show that the _present age_, material, mental and spiritual, is the legitimate result of the law of progressive development, the following propositions are deduced therefrom, forming a basis or platform from which to ask of the present—What of the future? Whither doth it lead?

First—All power, wherever manifested, is a unit.

Second—God is the source of all power, and the elements the subject of its application.

Third—Each attribute of God has its corresponding material element.

Fourth—All the material elements constitute the material world; all the spiritual elements, God.

Fifth—There is nothing contained in creation outside of the power of God, on the one hand, and the elementary principles on the other—the first positive, the last negative.

Sixth—Nothing can be added to what was; nothing taken away from what is.

Seventh—All the diversities in nature are the legitimate effect of the power of God, operating through and upon different elements, and different proportions of different elements, contained in nature, the diversity being infinite, because the material and producing power are infinite.

Eighth—Man, collectively, being the representative of all the material and spiritual elements, the individual diversities observed in him are the legitimate result of the different relative proportions of these elements contained in his organization.

Ninth—The present is the result of spiritual principles acting upon and through the material elements during the eternal past.

Giving a comprehensive glance at the world it will be seen that _government_ of some kind is everywhere established, which purports to rule the people embraced within certain geographical boundaries. An analysis of each form, from the crudest and most barbarous up through all the modifications of civilized government, will discover that each government was a true exponent of the character of the people by or over whom it was established. Every country, as it advances in intellectual and moral development, demands modifications in its government adapted to the improved capacity of the people. Hence, as the character of the governed progresses, so must that of the government keep pace with that of the governed, else the power behind it will rise to its _might_, and _sweep it away_.

There is but little doubt that the government of this country is the highest form now in existence on the earth; but to show how crude and even barbarous it is, reference only has to be made to the terrible conflict it has just survived, which became inevitable and necessary as the only practical demonstration of the power of the principles upon which it purports to have been founded—that all men are born free and equal, and entitled to certain inalienable rights, among which are life, liberty and the pursuit of happiness. This proposition was made fundamental by great and good men, the representative lights of the country at that time, standing far in advance of the general mind. Liberty and equity had burst upon their souls under the sway of tyranny and oppression, which became so odious that anything was preferable to them, to longer enduring its injustice. In this land, far removed from that where freedom could not lift its head—with a mighty ocean rolling between, they felt they had found a secure asylum from further oppression, and a land where their new-born hopes could be realized. But, unfortunately, all who came to the _New World_ had not these hopes and anticipations; some there were who still desired the strong hand of the tyrant to sway; and, thus invoked, it reached even across the mighty deep, and sought anew to enslave these new-born sons of freedom. Submission they never thought of—resistance was their only theme; and most thoroughly did they resist; through the long conflict that ensued, carried on by them under every conceivable disadvantage, their hopes never completely died out; and at last—triumphant over the crown—freedom reigned!

It cannot be wondered at that souls rising from such a conflict as the Revolution, triumphant, should assert so broad a proposition in behalf of equality as they did at the commencement of the struggle; nor is it wonderful that the great majority of the people did not understand, or did not have a full perception of the principle for which their representatives periled their lives and fortunes and pledged their sacred honor; but principles which were but partially discerned by the Fathers of the Republic have now grown into rules of action enforced by the sanctions of fundamental law; slavery of the body is no longer possible; the verdict of the majority of the people proclaimed it “behind the age.”

The South, recognizing this fact, knew that separation from the progressive mind of the North was the only chance for the continuance of a system which furnished so many excuses for physical, mental and moral lethargy; and in their attempt to separate, they precipitated a conflict in which history repeated itself, and freedom came out triumphant; thus what sprung from the seeds of tyranny and oppression, left scattered here and there by those who made that broad declaration, have been finally uprooted, and never more can take root and flourish under the scorching blaze of freedom's noontide sun.

That physical, mental and spiritual lethargy was the condition of the South under the system of slavery all statistics touching this point indisputably attest; and the verdict of fifty years will pronounce the abolition of their system the greatest blessing God has yet vouchsafed them; it has opened the door of progress for all things, material and spiritual, and has rescued from the barbaric chains of the past a country more favored by God, in the bestowal of natural advantages, than any other on the face of the globe.

The general love of freedom, because it is an inherent right, is one of the first evidences the soul presents that it is growing from the boundaries and control of the material, from which it sprang, into those of the spiritual toward which it tends. When this love first takes root the soul has attained that degree of development wherein the spiritual has the superior control of the individual, resulting from the predominance of the spiritual over the material.

The fact that the general sentiment of the country demanded that slavery should no longer exist within its boundaries, is a very significant one, when considered in connection with the tendencies and prophecies of the present; it shows that the capacity and desire for freedom is being rapidly developed in the human soul; it indicates that the mind begins to appreciate what freedom really guarantees to its votaries in its broadest signification; it begins to recognize the glorious truth that every soul will, sooner or later, demand and receive all its rights.

The demands of public sentiment, which have already resulted in modifications of the constitution of the country, will not stop at the door of African slavery, which it has thrown wide open; there are many other systems of slavery still left to be abolished; while they do not all enslave the body, they so fetter the soul and the mind, that their influence is even more pernicious and galling than the enslavement of the body.

The African slave, toiling under the burning sun in the cotton, rice and sugar plantations of the South, was virtually in possession of more freedom of soul than are many of the white race, even in our own midst. Look into these things, and see if, while you have "cast the mote out of your brother's eye," you have not a "_beam_" in your own; these, however numerous, will in turn and time demand of the people and of the government, when in its province, such attention as may be required to extend freedom in all directions where "life, liberty and the pursuit of happiness" legitimately lead.

The history of the past as well as the tendencies of the present prophecy with distinctness and positiveness that the demand will soon go out, not only for a government founded on equal rights to all, but whose laws shall be administered with justice and equity, guaranteeing freedom of body, mind and soul to every living intelligence.

From evidences rapidly accumulating, it is believed that this country is ripening for such a form and administration of government; but in the present condition of society and of servitude to its customs, the imperfect and partial manner of arriving at representation, and of making and administering law, such a reform cannot be inaugurated; that is to say, although such a reform would be acceptable to and welcomed by the country, and will soon be demanded by it, as yet it is impossible to organize an effort, strictly within itself, that could effect it, because there is not a sufficient concentration of understanding upon the requirements to be met, nor of wisdom enough to draft for these requirements adequate laws and forms of administration. Were such a code prepared and submitted to the people, do you think it would be rejected?

In the earlier days of the republic legislation seems to have been conducted upon constitutional principles; but in these latter days it has so far departed from its seeming mainsprings of action that it is safe to assert that legislation, founded strictly upon considerations of principles of justice and right, is unknown in the land. If sometimes a great principle is demonstrated through legislation, it will invariably be found upon strict investigation, that the legislation was not predicated upon the principle, but upon some personal or party benefit expected to flow therefrom; the _principle_, therefore, stands under obligation to the expected benefit, and to the party _needing_ it, and will doubtless, in its impartial operations, _remember_ them. While this condition is a perfectly legitimate one, flowing from adequate producing causes, there are individual minds and souls, by thousands, who rise in their capacities for government out of it, and demand reform and the essential truth of Principle.

Government may be compared to an individual who, having committed some infringement upon the law of justice, is impelled, by the position it forces him into, to continue the practice to sustain himself from falling; but as a system of injustice cannot be perpetual, fail he must, sooner or later; and the longer it is delayed, the more complete will be the wreck and ruin when it comes;—as with the individual, so it must be with the State. Once started upon a system of law-making and executing not founded upon principles of justice and right, the course must be pursued and sustained by further enactments, either to _cover_ the deformities of the previous proceeding or _hide_ its purposes, and unless righteous judgment come to the rescue before the course has led to wide-spread and apparent corruption throughout all its channels of administration, it must eventually culminate in the downfall of the government, if not in the destruction of the nation.

Policy, not principle, is the ruling power behind all present legislation. Policy, inevitably and indiscriminately, leads to corruption. Corruption, obeying the inherent laws of its own nature, untouched by and beyond the control of the enactments that first gave it life and afterward fostered its growth, must culminate in certain destruction to all parts involved, whether it be within the body human, the body corporate or the body politic.

Did the Republican party, as a party, desire the freedom of the negro simply and solely because it was one of his natural rights? Would freedom have been extended to him by that party had it been positively known that all his influence would be used against it? Or would the Democratic party, as a party, have opposed the enfranchisement of the negro had it been known that he would become its political ally?

Judging from the indices of the past, it is fair to suspect, at least, if not to conclude, that the Republican party is expecting another such exigency as existed when it was found politic to extend freedom and suffrage to the negro; and in the question of female suffrage, for which the demand is now being earnestly made, there is but little doubt that it sees another means of salvation in the future, and seeks to postpone the question until the exigency shall become more imminent and dangerous. It may be argued that the Republican party was organized upon the principles of freedom. If this were wholly true, it would be also true that it had no sooner become a party in power than it resolved itself into a tribunal to define the limits for the application of the very principles that had placed it in power; thereby endeavoring to prostitute the principle to subserviency to the policy of its leaders, instead of calmly and firmly following where it would legitimately lead; like all parties and sects, of previous origin, it built upon a principle, and then, instead of wisely following, recklessly attempted to guide it.

With all the prestige of possession, and of being the acknowledged representative of the principle which had carried it into power, the result of the late elections began to be feared by the party, because its leaders knew they had driven it from its birthright, and led it after strange gods; and, had the opposing party been actuated by true progressive principles of justice, no man, however popular in himself, could have saved it from destruction.

Conscious of having departed from the principles that gave it power, the Republican party is even now seeking every means within its grasp to fortify itself behind measures looking solely to success in ’72; but it is prophesied that ere that time there will have sprung into existence another party that will not be the mere professed representative of freedom and equal rights to all, but the actual, living, moving, irresistible incarnation of those principles.

The lines of policy pursued by party leaders, and the channels of corruption opened by the executive officers of the government, have produced a result so wide-spread in its influence and ramifications that, instead of their being under the control of the government, they exert a vast if not controlling power over all its actions; it is not necessary to go beyond its own records to establish this fact; every newspaper in the country teems with evidence in point; the clergy have deemed the situation dangerous enough to hurl the anathemas of the Church against it; the dramatist and the artist, the poet and the philosopher, have each dealt his blow, while the “toiling millions” everywhere cry for reform.

So general and earnest has the demand for reform become that something must be done; the gathering masses of corruption all over the body will soon have ripened to bursting; and who can tell how much the body itself has become involved. May it not be feared that it does not possess sufficient recuperative purity and strength to stand the shock? Could the enlightened mental, moral and spiritual elements of the country which are possessed by those who stand in the front ranks of the advancing column of progress be combined into organized action, they might be able to arrest the abnormal growth of corruption, and, by strengthening and stimulating the sound members of the body to co-operative action, restore the whole system to its normal condition.

The machinery of the government has become so complex and unwieldy—so full of departmental and petty offices—that it is utterly beyond the power of one man, though he be “_a great and mighty_ President,” to understand and control it.

The tendencies of the government being dangerous to the liberties of the people, their demand for reform is earnest, and must be heeded. But where will reformation begin? To whom must we look for relief? If we go to Congress with the Constitution in our hands, and demand such legislation as would give practical efficiency to the preamble and charter of freedom, they may possibly pay sufficient attention to the subject to pass a joint resolution setting forth that, while certain inalienable rights seem to be guaranteed to all, still Congress must be the dispensing power and judge of its application; and that it has decided that the negro shall be the first on the list—next, perhaps, the Indian may come in—next the Chinaman, and all the ends of the earth—except woman. Yes, go to Congress for relief from onerous taxes, wrung from the blood and bones of the laboring poor to fill the coffers of government vampires, and they will answer you by passing some new _Revenue Act_, in whose cunningly prepared articles will be found traps set for the people's money, which the trained bands of political party secretly manage on joint account for themselves and their party leaders; it will answer you by granting new subsidies to corporations already grown rich from the fruits of the labor of the people; by granting to powerful monopolies still further privileges increasing their power through bribery and corruption to make subordinate the welfare of the country to their own selfish purposes, and by favoring all schemes for the _centralization of power_. Such being the answers to your demands, there is still a tribunal to which you can appeal, which in all time past has heard and answered the _demands of the age_.

In the system of _special_ and _class_ legislation causes of corruption and the downfall of governments may always be found; it is the bane of the nations, whence flows that subtle, entrancing poison that permeates all the arteries and veins of a country—so quietly and alluringly to the people, that, before its effects are suspected, the vital principle of the government is destroyed, and the lifeless form finally falls to rise no more forever; or, if the spiritless form be still upheld by the usurper, it is only retained as "a cheat and a delusion" to shield the person of the tyrant who has enslaved his victims in the name and under the guise of liberty.

TENDENCIES AND PROPHECIES OF THE PRESENT AGE.

[Revised from the American Workman of Oct. 16, 1870.]

NO. II.

The subject of government and the solution of all its difficulties seem to hinge upon the question, Where does God's government drop its sway (if it does so at all), and where does man take it up, on his own account, by inherent natural right, guaranteed to him by the law that gave him being? The only modification of this question required to be considered is, How far man is or can be the authorized, competent agent of the Almighty in working out His purposes? To solve all these questions it becomes necessary to determine what the fundamental principles of government must be, to be in harmony with the laws of God, and to adopt them and to follow them out to all their legitimate conclusions and results, discarding everything else. In such government and legislation the eternal principles of right, which are God's laws, are in full force and effect, and _man_, thus far, an authorized competent agent in the administration of His decrees in the material world.

Whether a government founded or administered upon any other basis than the eternal principles of right and justice can or cannot be enduring, is a proposition the simplest mind may solve. Progress is from the lower to the higher; in its certain and irresistible march all systems and things that have risen out of the circumstances of the times to which they belong will be swept away to make room for the new and the better; but principles and self-evident truths that were contained in such systems will endure to be incorporated into all future systems.

There can be no higher form of expression than that life, liberty and the pursuit of happiness are "_inalienable_" rights to _all_; and, being such, it is safe to assume that it will always remain as a fundamental proposition in the organic law of this country; and legislation will be required to guide itself by it, instead of being its exponent.

Change upon change will come in the future, as it has in the past, until government will become so simplified as to have for its foundation nothing but an annunciation of general principles of justice and equity, as self-evident truths upon which all legislation must be based.

Passing, for a time, the consideration of the principles of government, it may be well to inquire into the injustice of some of its present details. All men, and women, too, are _born_ free and equal, entitled to certain natural rights, which no government has the right to take from them. While every man and woman is a result of the general law of procreation, there are distinguishing points peculiar to each, which renders every _one_ different from every _other_; thus no two persons can be so precisely alike as to make

their individuality the same; consequently no two persons are governed by the same internal and external mainsprings of action and influence. Let the same power and influence be exerted upon different individuals, no matter how nearly they may _resemble_ each other, different results will flow from each, the character of which will be absolutely determined by the status of the development of, and the relations between the material, and spiritual elements represented in the individuals acted upon. No argument is needed to prove this proposition; and the legitimate deduction to be drawn from it is, that no judgment of the action of the individual, by others, is just that does not take into consideration all the various points in character and influence under which action is produced.

It must not be forgotten that all thought and action on the part of an individual is the legitimate result of some competent producing cause, operating by natural law. The cause being competent, the law of operation natural, and the result consequently legitimate, can another's idea of right step in to sit in judgment over the action, and render a verdict of justice to the actor? Or, can any number of individuals determine what the demands of justice are which God himself has declared by the mouth of all His holy prophets, material and spiritual. "Judgment is mine; I will repay, saith the Lord."

No one can hope to escape the judgments of the eternal law, or to hide himself from God's officers of justice; but must by them be brought before its stern, undeviating bar, to receive its unpardonable sentence. But, says the objector, this does not satisfy me, who have suffered from the offence. What if it does not satisfy you? God is satisfied; and are you greater than He, that you may question His justice? If you are not yet satisfied, God will most surely satisfy you in His own good time.

Look into your statutes, and within them, find their own stultification. They assert that no criminal shall be subjected to two trials and penalties for the same offence; but, in the face of this righteous rule, and with the positive knowledge that God has already tried, convicted and sentenced the murderer, the courts of the country take possession and control of the criminal, proceed to try, convict, condemn and hang him by the neck until he is dead. Rest assured God will not overlook this attempt of yours to forestall his judgments.

We stop here to make a broad assertion: For man to affix certain definite penalties as punishment for so-called crime is to arrogate to himself what alone belongs to God!

Stumbling-blocks are constantly found in the path of progress, against which the earnest traveler finds himself precipitated; these consist of the ideas of the past, clothed with form and expression, and which were set up by their conceivers as "guides and lights" of their times, for those who groped their way by such assistance. The earnest seeker after light finds these set up all along his path, declaring "thus far shalt thou go, and no farther;" but he, catching a glimpse of the light so bright beyond, clears the obstruction by a single bound, and goes on his way rejoicing, seldom deeming it his duty to turn upon and cast what to him was but a hindrance from the path of progress, so that others coming that way should not encounter it, who perhaps might lack the power to surmount it. "Let your light shine" so that those who come after you may be aided thereby.

A single argument upon the question of the relations between debtor and creditor, which is maintained by the present laws, will be sufficient to illustrate the whole subject of customs, authorities and laws, which are obstructions in the path of progress. The time was when imprisonment for debt was authorized by law in all the States of this land of freedom (?); but the spirit of progressive justice has been at work until but few of the States now retain this libel upon Christian civilization to disgrace their statutes. Imprisonment for debt! What good ever resulted from it? The malignity of the creditor may have satisfied itself by still further humiliating the broken spirits of the debtor; but the creditor, by such action, places it still further beyond the power of the unfortunate debtor to satisfy the demand. It is asserted, without fear of successful contradiction, that the same deleterious effects generally flow from all similar laws. All kinds of crime are but species of debt, and the same rule applies with about the same force to its laws and penalties. Imprisonment for debt has been pretty generally abolished, but still our statute books are laden with laws to enforce collection.

A philosopher and economist, not long ago, fully investigated the relations between debtor and creditor, and the practical results of the laws now in force, and arrived at the "deliberate conclusion" that the costs attending the attempts to collect debts by legal process were three times the amount collected; not a very flattering commentary upon the policy of the law, and certainly not a paying investment to the crediting part of our community. This conclusion may at first thought appear fallacious; but when the expensiveness of courts, and the immense incomes of lawyers who practice at their bars, are considered, the afterthought will fully sustain the conclusion. It is believed by many that if there were no laws at all to enforce collection, there would be many less _bad debts_; even now a debt of honor is held by public opinion to have precedence of those which the _law_ claims the right to enforce.

The thinker of ordinary capacity will see at a glance that an immense amount of labor would be withdrawn from the courts, which now bears heavily upon the people, not only in the form of taxes to pay for court-houses, jury-rooms and judges' salaries, but in the waste of time employed in jury-boxes by men dragged from their inevitable toil, and held as prisoners, while their wives and children are often suffering, and even dying, from the want of their care and attention at home. Contracts should be so well defined as to admit of no misunderstanding; and if there was no method of collection and enforcement, there would be very many less disagreements; hence, in no light in which it can be viewed, does our present system commend itself to the wisdom and justice of the reflecting; on the contrary, it throws open the door for cunning and knavery to enter to test their strength through technical evasions and blind inferences, practiced, on the unwary and ignorant by the "_Quirks_, the _Gammons_ and the _Snaps_," who, as _vampires_ of the time-honored profession they disgrace, feed and fatten upon the misfortunes of the deluded, long-forbearing, long-suffering _children of toil_.

It may be safely asserted that a very large part of _all law_ contained within the statutes of the world, when analyzed, will present about the same deleterious results in practice and in the opportunities presented for infringement and subsequent evasion of their penalties that inevitably flow from all laws for the collection of debts.

The time has probably not yet come for the abolishment of all such laws, but the time has come when the relations of individual debtors and creditors should be left to the control of general principles of justice, which declare that a contract once fairly made, an obligation once fairly incurred, can never be discharged until satisfaction shall have been entered upon the record by divine justice.

TENDENCIES AND PROPHECIES OF THE PRESENT AGE.

[Revised from the American Workman of Oct. 30, 1870.]

NO. III.

When it is considered, how much the useful portion of life is dependent upon the preparatory part, the character of the influences brought to bear during that part, and the manner of their application, become a subject of deep importance. Education has received the most special attention from scholars, savants and professors; but they seem to have forgotten or to have ignored the fact that within the mind is contained the germ of all acquirements, and that teaching by rule merely what others have said or written, cramps and dwarfs the mind which, under a more natural system, would more rapidly and more healthfully develop its latent powers, through its stimulated efforts to evolve ideas connected with such facts and phenomena as may be exhibited to it, and thus become a part of the mind itself.

Instead of training the mind to rely upon method, books and authorities as rules, it should be encouraged to form methods of its own. The mind should be questioned, and its answers listened to, instead of being furnished by the teacher.

The mode proposed has many decided advantages. It inspires self-reliance, disciplines the mind to think for itself, accustoms it to express its own conclusions in its own chosen language, leads to clear and comprehensive forms of expression, gives decision and confidence, and tends to produce individuality of thought and character.

The Children's Progressive Lyceum, instituted upon this idea, has already been inaugurated, and should receive the careful and unprejudiced attention of all interested in educational reform. Children who have been under this system but a few months are able to stand before an audience, and, in a clear and comprehensive manner, speak without embarrassment upon any subject comprehended by their minds. The coming generations will acknowledge a debt of gratitude to the founder of this system which no depth of respect or reverence could fully express.

No proposition can be made which will be more readily accepted by the general progressive mind than that, as the world advances in knowledge and wisdom, its general welfare becomes more and more dependent upon reciprocal interests; that is to say, as _persons_ and _nations_ become more and better individualized, their reliance upon interests outside of themselves becomes more positively and distinctly defined; thus a system of mutual dependence and reciprocal interests is every day being more widely inaugurated, which will continue to spread until the whole world will be brought into harmonious co-operation. This is _commerce_! Commerce, to the material world, is what thought is to the spiritual—interchange and exchange of material product in the one and of spiritual in the other—hence no restrictions or embargoes should be placed on the one which would not be legitimate if placed upon the other. The dependence and independence of each is mutual and general.

Restrictions upon commerce is a system of commercial slavery, flowing from _politic_ and _special_ legislation, and is in violation of the eternal principles of right, because it renders equality in interchange impossible. If it is the right principle to restrict commerce between nations, it extends to States, to cities and to individuals as well.

Under the rule of an unrestricted commercial intercourse throughout the world, the principle of supply and demand would control the movements of commerce without the aid of legislation; and, when once fully established, it would give stability and security to production everywhere. The products of the world entering into commerce would localize themselves where they naturally belong—where most could be produced with the least labor; and, population obeying the laws of equalization, would adjust itself to the demands of the respective interests of productive labor. This is a vast problem, in the solution of which the whole world is vitally interested, and one which, sooner or later, must be solved. If its solution were possible _now_, coming generations would look back and bless us for the solving. An international congress should be called to consider the subject, and to take proper measures for the inauguration of a system of general economy in production and consumption. The prophecies of the age point to this as a reform of sufficient magnitude to demand the immediate attention of the nations, and to call for a _Christ_ to rise up for their salvation more powerful than the Democratic Party.

The political, national or personal advantages which are supposed to flow from restraints upon commerce, have nothing to do with the question of general reform. While it is the duty of every nation and every individual person to press forward the work of reform upon general principles, each nation and person must always keep in view the law of _self-preservation_, otherwise individuality will be lost in the struggle for supremacy, which has hitherto characterized the legislation of nations and the conduct of individual persons. The great principle of unrestricted universal commerce can only be practically established by universal acquiescence in its wisdom and justice. When legislation shall conform itself to general principles, instead of sectional, local or personal policy, and when its course shall be shaped by such broad action, it may be safely prophesied that the government it represents will be perfect and perpetual. Commerce will then obey the law of progress, and rise from the petty policies of nations, which strangle its development and limit its benefits: it will rise to be conducted upon the dignity of principle, untrammeled by policy; and on this platform the world will unite in harmonious prosperity under a universal government, not limited even by the boundaries between the material and the spiritual world.

Underlying all advancement and prosperity, material and spiritual, is action—motion—which, guided by intellect, results in _labor_, without which the world would be as though man had never been; for no form of creature below him has ever left permanent artificial beauty, systems of economy or usefulness as the result of its workings, except in so far as the form itself may be accounted such.

What, in two hundred years, has so changed the face of this country from the wilderness it was to the teeming garden it is, dotted all over with the habitations of men? What has produced the floating palaces that everywhere walk its deep waters “like a thing of life?” What has united all its distant parts by iron bands, along whose guiding lines those other representatives of _art_ and _motion_ speed, almost outstripping the wind? What has overcome time and space, and is now extending its arms to embrace the globe, that we may speak, and that the ends of the earth answer our call? Marvelous demonstration of the rapidly growing mutual and reciprocal dependence of the children of men! What has made the wilderness to blossom as the rose? What has achieved all these glorious, god-like results? Labor! labor! labor! physical, mental and spiritual labor!

Labor, therefore, is the fulcrum of the great lever of progress, lifting humanity from the material up to the spiritual realm. One short century ago nearly all physical labor was performed by the hands of man. Since then the mind has come up to the work, and rescued the body from the laborious servitude of former times; and now a single mind, directing a single machine, produces an hundred-fold more than it could when acting through its own personal machine. The inventive powers of the mind will continue to produce more labor-saving machines until labor directly with the hand will be almost, perhaps entirely, superseded.

The products of the mind, when compared with purely physical labor, are of inestimable value, and the great distinction everywhere recognized in their relative compensations is still too limited. No argument is needed to establish the dignity of labor; it has established itself in becoming the architect of the great future, by building the past and the present.

Out of the multiform phases of labor, questions will arise which will require for their adjustment equitable rules of compensation; the best talent in the world can find ample scope for useful employment in the solution of the numerous problems growing out of this vast subject. _Labor_—physical, mental and spiritual—finding itself in a position of injustice, is in a state of constant irritation and discontent, and legitimately seeks redress through the organization of associations to control its price; but it is at least questionable

whether such combinations have been productive of any permanently beneficial results. If it could be perceived and comprehended, there must be, in the nature of things, perfect and complete harmony in the practical operation of all the working elements or agencies, not only in this world, but in the boundless universe.

This problem may find a practical solution in co-operative labor associations, in which the members share equally the profits upon what they produce.

Suppose the entire labor of the country were conducted upon this just principle, what would be the result? The rapidly accumulating wealth of the country is the result of labor; if the united labor of the country, producing this increase, should henceforward share it equally, the result, in time, would be the _equalization_ of the wealth of the country, which is now rapidly growing into a necessity, to modify the luxurious habits of the rich on the one hand, and the crying evils of poverty on the other, which are rapidly engendering an antagonism, which will continue to increase in volume and intensity until it will culminate in a storm that will consume the elements of discord in the same manner (and upon the same immutable principles) by which African slavery was abolished in the Southern States of this Union.

A careful investigation of the co-operative principle will show that it is not only possible, but perfectly simple and practicable, and that it is full of glorious prophecy to the vast numbers who are now “ground to the earth” by the condition of actual slavery to the ordinary demands of nature which is entailed upon them from generation to generation, through the operations of false systems, which were founded upon and which are sustained by injustice and usurpation.

While viewing this subject in its practical aspects, it must not be forgotten that _it_, too, is intimately connected with progress, and subject to its decrees.

It is a well-established fact that the powers of endurance of the physical system are growing less, generation after generation, while the mental power is increasing in about the same ratio; the legitimate deduction from this fact is in perfect harmony with the general progressive tendency of all things leading from the purely physical to the spiritual, from which we may safely prophecy that the time will come when all labor will be performed by the mind, and when it shall have acquired perfect dominion over the material. The necessity for physical endurance will then have ended. The tendency to such a condition, though it has been, is, and may continue to be gradual, is nevertheless positive and well-defined.

Intimately connected with the subject of labor, and the tendency to perform by the agency of inventions what still devolves upon the direct application of physical strength, is that of supplying the demands of the body. The food used now is very different from that of a hundred years ago. Some who recognize this fact argue that the change of diet has produced the change in the physical condition; but reasoning from analogy, and applying the general rules of progress, leads to the conclusion that the changes in the relative conditions of the physical and mental, by which the latter asserts superior control, have rendered a corresponding change of diet necessary; hence it is fair to conclude that the change grows out of the necessities of the consumer, and is not the producing cause in the premises; in other and general terms, the physical system demands and should receive appropriate supplies.

Hundreds of people who once made use of the flesh of swine have entirely discarded it from their boards, instinctively feeling that it does not meet their present demands, and there is a growing distaste for it. Common observation shows that all kinds of flesh are gradually falling into disfavor, especially among those who labor mentally or are devoted to spiritual things.

As the physical system is gradually being relieved of labor and the consequent waste of its energies, the character of food it requires necessarily changes, and in the place of physical strength to be supplied is that upon which the brain can draw to replenish its wasting stock; the failure to recognize these demands causes very much of the dyspepsia from which those who lead sedentary lives suffer so generally; these should discard those articles of diet that principally contribute to build up the material, and use such as will impart strength to the mind.

There are quite a number of well-authenticated cases of the actual subsistence of the body upon the elements contained in the atmosphere a sufficient length of time to show that it could be continued indefinitely if the proper conditions were preserved. One of these cases in the State of Kentucky has remained seventeen years in this condition; one in Chicago nearly four years; there is one in Brooklyn of three years’ duration; and a number of others from ten to sixty days. In this condition the physical system becomes entirely renovated, purified, and almost transparent, and the spiritual faculties intensified many fold.

TENDENCIES AND PROPHECIES OF THE PRESENT AGE.

[Revised from the American Workman of Nov. 20, 1870.]

NO. IV.

Arguing from the fact that the character of food subsisted upon is gradually changed from the purely physical to the more refined and rare, in connection with that of exceptional cases having existed, in which supplies were drawn from entirely different sources than digested food, leads toward the conclusion, at least, that the time will come when men will have grown out of the necessity of supplying the wasting energies of the body and mind by the use of food, and into that refined spiritual condition in which he can draw directly upon the elements which the atmosphere does or will furnish to supply all his demands. All the arguments nature furnishes point to this condition. All know how very important it is to have a plentiful supply of pure air; but how far this goes toward furnishing the elements of supply demanded by the body, the deepest inquiries have not decided.

In a given case, the actual amount in weight that is furnished the body can be determined; deducting the weight of the excretions and palpable secretions, it is supposed the difference is consumed by some undefined process within the body; but who can tell how much and what the system takes directly from the atmosphere, or how much it gives up to it, that we have no means of defining by weight or otherwise? We also know that the atmosphere maintains an immense pressure upon the body, and that it involuntarily resists this pressure; this could not happen were there not some well defined and intimate relations between the two upon which man, as the object, must be greatly dependent.

Another strong and pointed argument is to be found in the process sometimes resorted to to sustain life: in cases of great prostration of the physical system, under exhaustive disease, when the means cannot be supplied through the medium of the stomach and digestion, they are furnished by being absorbed into the system through the pores of the skin.

The constant death and decay of all the materials upon which we feed, besides all that vast amount not drawn upon directly, is continually giving off to the atmosphere the same kind of elements which the body retains and uses from supplies of food; as they exist in the atmosphere in the form of elements, and there is a demand within the body for them, it is only necessary to create and maintain the means of supply to solve the problem. A glorious prophecy comes forth from the tendencies of labor toward the mental, and the accompanying necessity for modifications of diet, adapted to the many gradations man must pass through to reach a purely spiritual condition.

The physical system has been the accredited medium through which the spirit within it—the real man—has wrought, and still is, in all individuals who are not beyond the point where _spirit_ becomes the predominant and governing characteristic. In the present, however, there are scattered here and there among the masses individuals who have passed—are passing—or are approaching that point in which the spirit, at times, acts independently of its material machine in which it has been fostered and cultured, and gives positive proofs of an existence within the body of an individualized life, which can and does act without the agency of the body, and performs functions before impossible. There are a thousand persons, at least, in this country who have a sight entirely independent of the physical eye, which overleaps the boundaries of physical vision; penetrates the barriers of external sense, tears off the mask of hypocrisy and deceit, detects the motives and mainsprings of action, and lays bare the heart of man. While comparatively but few have attained this, all are approaching it. What does Paul mean but this when he says, “Now we see, as through a glass, darkly; but then face to face”? When the spirit-eye shall have fully pierced its barriers of flesh, when the body shall have become subservient to the spirit, instead of the spirit being dependent upon the body, when we “shall see as we are seen, and know as we are known,” how radical the changes, and how rapid the strides of advancement will then be!

Reason for a moment upon the effect that would be produced were every tenth person suddenly endowed with spirit-sight, and compelled to demonstrate it by exposing the hearts and the lives of all the rest. Where could oppression hide itself? Where could the lusts of the flesh plot their treason against the sovereignty of the spirit, beyond the range of _spirit vigilance_—this new safeguard of human society, the eternal law of progress, which is now unfolding? In such a condition of things, courts of justice, with all their attendant judges, bailiffs and attorneys-at-law, would find their occupation gone. Prisons would be converted into asylums and workshops for the weak and unfortunate, and their keepers into superintendents and teachers. Churches would be converted into lecture-rooms; and preachers, now hurling their anathemas against unrepentant sinners, would become professors of the great principles through and by which the world, and all things, have been brought from the primary condition thus far on their march toward the _perfect_.

Many individuals know that they are under the surveillance of this spirit-sight, and demonstrate in conduct its beneficent influence; but the capacity has not yet become sufficiently general to compel the recognition of its efficacy by the public mind. As the rising

sun first gilds the mountain's loftiest peak, next the hill-top, then glides along the inviting slope to the universal plain, where all creation rejoices under the refulgence of its noonday glories—so comes this _rising light_, to illumine the hearts and souls of all when it shall have reached the zenith of its mid-day glory. As the beams reflected from the mountain top are of the sun, and not the mountains, so are these spiritual rays of the spiritual sun, and not of the individual reflecting them, or through whom they may chance to shine. Verily, verily, I say unto you, this people vaunteth and puffeth itself with knowledge, but wisdom hath surely departed to the lowly ones of earth! Religion, clad in its robes "of purple and fine linen," faring "sumptuously every day," forgetting that Christ was cradled in a manger, and that His disciples were fishermen, continually cries, as did the "Pharisees and hypocrites" of old: "Can any good thing come out of Nazareth?"

The time is not far distant when the possession of spirit-sight will be accounted of the first importance, not to those only who possess it, but to the public generally, and will be sought for and made practical to the honor of its possessors and to the inestimable benefit of all. The time will come in the not far distant future when those who now cry out, "Can any good thing come out of Nazareth?" will bow, with becoming humility, before the later-day _fishermen_; for these will then occupy the places of public trust, and spirit-telegraphy, having superseded material wires, will convey the commands of God's accredited ministers from the central seat of Power throughout the world.

Where are all the great of the _past_; its orators, philosophers and statesmen; Confucius, Zoroaster, Moses, David, Solomon, Lycurgus, Demosthenes, Cicero, Bonaparte, Washington, and many others, of all nations and climes, to whom history points as having stood hundreds of years in advance of their times? Do they still live? and, living, are they idle? Are their minds withdrawn from subjects to which they were devoted in this primary school-house of the children of God? Are not their minds expanded to the comprehension of the great principles of governmental justice? Are they not better qualified to direct legislation _now_ than the wisest among us? If they still live as spirits, if they have had better opportunities of obtaining wisdom and knowledge pertaining to earth-life than we—can this world avail itself of their assistance to establish on earth the government of heaven? If the angel in the bush were possible, why may not angels manifest the wisdom, power, and justice of God in our legislative halls? Who will dare to assert that they are not even now seeking another Moses to lead "His people" up out of Egypt? Then will the prophecies of the present have reached consummation; then will commence the earthly reign of the King of kings and Lord of lords, as prophesied by all the holy prophets of the world; then old things shall pass away and all things become new; then _the Christ_ shall sit upon the throne, and from his inexhausted fountain of love, justice shall continually flow over all the earth, "as the waters cover the sea."

As vanish the heavy mists of the morning before the radiance of the rising sun, so will vanish the clouds that hang around the minds of man, and shut out the rising spiritual sun, for whose "star in the East" _wise men_ are continually watching; the sun that will rise higher and higher, and extend its rays wider and wider, until it shall enlighten the minds of all mankind, until the icebergs of ignorance, tradition and superstition are dissolved which now float in the ocean of progress—society, with its cankered, festering heart; commerce robbed of its legitimate function; labor of its recompense, and religion of its spirituality; education lacking wisdom, marriages forming "disunions," and women without rights.

All the false forms of the present must yield their sway to God's command—"Let there be light." The laws of God are never changed—though old as creation—they are ever new, ever sufficient for all the vicissitudes of life; they are ever full of wisdom, justice and love; they are written all over the face of creation, in the bosom of the earth and in the heart of man; they are uttered by the raging tempest that rocks the mighty ocean; in the terrible mutterings of the earthquake; in the fury of destructive battle, when hosts are hurled on hosts in fraternal strife; through all these the voice of God proclaims—"Let there be light," and there is light.

We also hear its whispers in the gentle zephyrs that stir the bursting buds and in the blooming flowers that lift their heads to drink the falling dew; in the hum of busy nature; in the gushing fountain; we see it in the gambols of the bubbling brook; in the mother's love for the new-born life; in the father's pride; in the unspoken joy of the maiden's soul, listening to the first sweet tones of love; in the magnetic ties of human sympathy which bind all mankind in a common brotherhood, and in the dawning light of heaven brought to earth by the angelic hosts to usher in the reign of universal justice, peace and love.

INTRODUCTION

DO WE EAT TOO MUCH? CAN WE LEARN TO EAT RIGHT? WITHOUT LOSS OF ENJOYMENT? WITHOUT CARE BEING A NUISANCE? WITHOUT SOCIAL INTERFERENCE? WITH ASSURANCE OF HEALTH? WITH INCREASE OF ENERGY? WITH INCREASE OF ENDURANCE?

* * * * *

TO ALL THESE VITAL QUESTIONS, THIS BOOK ANSWERS ONLY “YES.”

* * * * *

VERIFY THIS BY PERSONAL EXPERIMENT. IRRESISTIBLE DESIRE FOR PHYSICAL EXERCISE WILL FOLLOW, AS A MATTER OF COURSE, PROBABLY FRUITING IN USEFUL ACCOMPLISHMENT BY THE SAME INVITATION OF HEALTHY IMPULSE WHICH CAUSES CHILDREN TO PLAY TIRELESSLY. DO RIGHT YOUR FEEDING OF THE BODY. NATURE WILL DO ALL THE REST FOR YOU ARIGHT.

Introduction

DO WE EAT TOO MUCH?

(_A propos of the Scientific-Military Experiments at Yale University_)

Do we eat too much?

Nine out of every ten physicians tell us “Yes,” and tell us true!

How much too much?

* * * * *

Luigi Cornaro suggested that all persons in his time ate more than was necessary; most persons ate twice as much as was good for them; and some, who were extravagantly gluttonous, ate ten times as much as was their most economic need; and Cornaro, who was a dissipated wreck at forty, reformed his manner of eating and lived to be a hundred to prove his declaration.

Experiments carried on in this country and in Europe during the past five years confirm this estimate of habitual excess; but fortunately they have also revealed a natural protection, heretofore unappreciated, available to all, which can regulate the appetite to suit the real needs of nutrition and thus avoid the dangerous excess which predisposes to discomfort and disease.

* * * * *

Luigi Cornaro lived more than three hundred years ago. His charmingly frank and interesting autobiography has been published in English upwards of forty times in different new editions, and no one has disproved the possibility or probability of his claim. We all know that Cornaro was right. We know, in a general way, that the great Italian dietitian and philosopher was wise and uttered wisdom, and we are told that most, if not all, of the diseases which pain, worry, and afflict us are caused by indigestion or mal-assimilation of food, the result of some indiscretions of eating. The questions then are “What are our indiscretions?” “How can we avoid them?” and “What is the new discovery that will protect us and, at the same time, add to the pleasures of the palate and of

living?”

The answers to all these queries will be found herein, as will also an explanation of the very active interest which is being taken just now in the problem of human nutrition by scientific and military authorities, as evidenced by the Yale investigation.

The author has, in collaboration with several others, found a way how _not to eat too much_ while eating _all that the appetite desires_, and in a way that leads to a _maximum of good taste_ and at a _minimum of cost and waste_, but it is necessary to test many persons of different physiques and varying temperaments, and also to test other methods of attainment of economy, to learn what is best for general application, and that is what is being done at Yale.

* * * * *

The cost to the pocket that is saved by economic nutrition is of little matter as compared with the saving of the waste of energy and the menace of disease.

* * * * *

Nature certainly never intended that we should weaken, depress, and distress ourselves in the way that is common to present-day living, as is made evident by the prevalence of discomfort and disease relative to our daily food. Nature’s plan of evolution does not work that way in general, does not retrograde in the progress of the improvement of plants and dumb animals, and certainly does not intend that Man, the First Assistant of Nature in the cultivation of things and in the domestication of the powerful natural forces, should suffer and become degenerate contrary to her general law.

If we are agreed upon the foregoing, let us ask ourselves a few questions.

Without any undue egotism, may it not be possible for a generation of human beings, who have progressed so far in intelligence as to be able to move things by steam, to communicate across the ocean even without wires to guide our messages, and to see clearly through objects that are as dark as night to the unassisted human eye with the aid of an artificial light, to learn the secret of right self-nutrition and practise it in a manner that will not deprive us of the maximum of pleasure which Nature invariably gives as a reward for conformity with her beneficent requirements? May we not assume that beings who have learned to breed and train horses to race with human intelligence, and to run, trot, or pace a mile in less than two minutes, may also train themselves to have the proportional relative speed, endurance, and longevity that has been attained by race horses through man’s care, and to enjoy the pleasure of living that is evident in these favoured animals, mere servitors of man though they be?

If this disparity of man is due to ignorance arising in self-neglect, which is the usual accompaniment of genius, may we not now, at the beginning of the pregnant twentieth century, rest for a moment from discovering, developing, and improving the world outside our personal selves and concentrate our attention for a while on learning to know and care for ourselves? May we not, at least, give “horse sense” attention to such a vital interest?

* * * * *

In the midst of the present confusion which exists among opinions as to the right conduct of life and activity, and the best manner and system of diet to be used to secure health and efficiency, it seems almost a vain appeal to call for concert of action in a matter of common and persistent neglect. Each person, as his own keeper, is careless, and in matters of bodily management no one feels called upon to be his brother’s keeper; but this is merely the lethargy of oversight and consequent ignorance, and this book is published to call attention to the oversight and to attempt to dispel the ignorance.

* * * * *

At the present moment of writing (October, 1903) there are quartered at New Haven, Connecticut, twenty privates of the Hospital Corps of the United States Army and three non-commissioned officers, under the command of Assistant Surgeon, Lieutenant Wallace DeWitt. These men and officers, while they are under regular army discipline and are performing duty in conformity with their oath of enlistment, are yet volunteers. They are from the same corps, if they are not the same men, which furnished volunteers to investigate the causes of yellow fever in Cuba, whose heroism resulted in stamping the fever out of the islands and in that more effectually protecting our coast states from its yearly incursions. These are the same men who generously refused to accept the offered bounty. This latter expression of exalted manhood is evidence of what humanity is whenever there is real need for heroes to serve the general good. They refused to _sell_ themselves as risks for money, but they freely _offered_ themselves as subjects of

scientific investigation for the benefit of their fellows and of mankind at large.

* * * * *

The duty that the soldiers are engaged in at Yale has no element of risk, and need not have any feature of monotony or tediousness in it, much less has it the romance of sacrifice, for it deals with an attempt to restore normality and does not consort with disease. But the service being rendered by these guardians of our health, these soldiers of hygiene, is even more important than was the service rendered in stamping out yellow fever, for it deals with an enemy much more subtle, treacherous, common, and deadly than Yellow Jack. Yellow fever calls for a halt and an immediate attempt at cure, and further, for stringent defence to extermination; but indigestion and the American plague, _dyspepsia_, work their evils slowly but surely to cut off our best men and loveliest women in their prime and to rob us of their richest product and of their maturest wisdom.

* * * * *

The investigation at Yale is a link in a chain of effort that has developed in logical sequence and has been planned to effect a cure of the common ignorance and practice relative to right human nutrition in its relation to profitable thinking and doing; and to discourage the personal neglect which has been responsible for the existing ignorance, this book is issued to show what may easily be done and what has been done, so far, in this direction. It is a compilation of important knowledge which has been born of recent scientific research but which is hidden away from common comprehension in scientific publications; and it relates the story of the development of which this book is an exponent. Herein are given the reasons why the government and the most eminent scientists in the line of researches in nutrition are coöperating so earnestly and so unusually in a commonweal inquiry.

* * * * *

About ten years ago, at the critical age of forty-four, the author was fast becoming a physical wreck in the midst of a business, club, and social tempest. Although he was trained as an athlete in his youth and had lived an active and most agreeable life, he had contracted a degree of physical disorder that made him ineligible as an insurance risk. This unexpected disability, with such unmistakable warning, was so much a shock to his hopes of a long life that it led to his making a strong personal effort to save himself. The study was taken up in systematic manner, account of which is too long to relate here; but the eager auto-reformer soon learned that his troubles came from _too much_ of many things, among them too much food and too much needless worry; and realising the danger ahead, he sought a way to cure himself of his disabilities by the help of an economic food supply, as did Luigi Cornaro; but what is even more important, he found a way to enjoy the smaller quantity of food much more than any plethoric luxury can give, and arrived at the method by a route that showed a means of conserving a healthy economy and an increased pleasure of eating, at the same time, in quite a simple and scientific manner, that any one may learn and practise without any ascetic deprivation whatever. Cornaro buried the real clew to his economic and pleasurable success with his body, owing to his vague generality of description of his method. The author is determined not to make the same mistake, and thereby bury _his_ key to a happy and easy life.

* * * * *

The secret of the method is all told in this book and is confirmed herein by both theoretically scientific and scientifically practical authority; but the experiments which are being conducted at Yale by Professor Chittenden, in coöperation with Surgeon-General O'Reilly of the army, of which the _Daily Press_ has given notice, together with experiments which are in progress in many university laboratories in this country and in Europe, are for the purpose of explaining the "reasons for things" by complete scientific reasoning, so that none may doubt the disadvantage and sin of dietic ignorance and carelessness.

The acceptance of the theory and method of the author at the great Battle Creek Sanitarium, after more than a year's trial, and elsewhere among curative agencies, and their adoption and use as the first requisite of treatment, of which the public have not so generally heard, are indorsements coming from practical, intelligent, and expert sources of experience and judgment, and hence they are of the utmost value and significance.

* * * * *

This introductory chapter is being written after the "clippings" of newspaper comment relative to the presence of the soldiers at Yale have begun to come in. The majority of comments are generous in spirit, but indicate a lack of complete understanding which this "Introduction" is intended to correct.

* * * * *

Some of the comments are couched in ridicule, and express pity for the poor soldiers who are being “misused” as subjects of starvation in an investigation which promises to make starvation a rule in the army. To the writers of such trifling and unfair paragraphs let me, one of the fraternity in an amateurish way, beg consideration of the following.

The campaign that has been started is against a common enemy of mankind, and of the American and English nations in particular. In our successes in agriculture, manufacture, and commerce we have cultivated insidious, luxurious temptations which bring all of us some ill and many of us, or our loved ones, fatal disease and premature death. The advance agent of these enemies of ours is Eating-and-drinking-too-much.

* * * * *

The officers and men of the army and the eminent scientists of our country and those of all nationalities who have entered into the campaign with us, and the great power of the sanitaria joining as practical nurses, demonstrators, and exponents of the reform, are all working for you and for everybody. It is voluntary service and has already cost some of the volunteers much time and patience and also a considerable sum in money.

* * * * *

You, gentlemen of the Press, wielders of the helpful or careless pen, have a conspicuous pulpit and a far-reaching influence. No one can escape you. In the search for the news of the day you are encountered at every turn in your editorials or your paragraphs. In this campaign we need your assistance to make the coöperation between the army and science easy and effective. They are too busy working for you and your best interest to stop to argue to correct your misunderstanding, but the cause will feel the benefit of your assistance.

Encouragement has powerful influence in stimulating effort and also in creating and conserving conditions in which men may “do their best.” What we are trying to learn is, what man _may_ do, under favourable conditions of knowledge and confidence, to relieve his body of the _strain of energy-taxing labour_ in disposing of the waste _which any excess of food imposes_. It is a constructive experiment and not a mere statistical measurement. Appreciation and applause assist; doubt and ridicule obstruct.

The soldiers and physiologists are too busy studying indigestion and possible proteid poisoning and what-not-other causes of intemperance, disease, and suffering to ask you to assist in spreading only serious report and right suggestion relative to the importance and purport of the investigation, but it is my privilege to ask it for the general good.

* * * * *

Just another word of introduction and then will follow some _postintroductory_ coincidences relative to the work in hand, and then an attempt to lay out a ten-page chart of the personal responsibility in the care of the body and the nourishment of the mind by aid of an economic and most satisfactory nutrition, so as to make conservation of energy as easy as possible and life well worth the living. The scientific support from the pens of professional observers is, however, the real meat of the book, for which compiler and reader alike are and should be grateful.

* * * * *

In serving in the humanitarian ranks in a commonweal campaign one should not need to use the concealment of modesty, nor should he fail to speak with all frankness. What are the motives behind all this energy to reform the eating habits of the people? The question has been so often asked that it is better thus publicly answered.

No one concerned in the campaign has any personal monetary interest in any kind of food, prepared or otherwise. The movement began in a suggestion carried by an accidental word given to the author by a friend, an old-time friend in Japan, and a friendship never to be forgotten, as related in the author’s book “Menticulture.” Pursuit of menticulture led further to the discovery that the best mental results could not be accomplished in a body weakened by any indigestion, any mal-assimilation of nutriment, any excess of the waste of indigestion. Then came the quest for the causes of mal-nutrition, which were soon found, by study of the natural sequences and by going behind the hypotheses of text-book authority, to arise in the careless ingestion of food, its neglect in the mouth, and the consequent glut of unassimilable excess within the body, necessitating enormous expense of brain and body energy to get rid of the excess.

When the secret of the potency for good of a rationally economic alimentation was revealed to the author, was confirmed by several colleagues of different ages and both sexes, and was tested by work and endurance measurement, and also by the test time, it became necessary to have given to it the indorsement of highest authority in order to have the information credited. The new rediscovery was a simple matter, something everybody thought they knew all about because it had been under their nose all their life and was one of the commonplaces of every-day living, but for that very reason it failed to receive credence, and the backbone of the doubt was habit--lifelong habit--and this was hard to break even in those who accepted the theory of economic nutrition as a logical conviction. It was also necessary to prove that it was not personal idiosyncrasy that favoured us, its advocates.

It is in pursuit of the latter desideratum that the officers of the army, the scientists, and the great humanitarian health-restoring institutions have entered upon conclusive investigations, each in their own way, to chart out a law of economy that will be generally applicable and which, it is hoped, can be understood by kindergartners and mothers for the benefit of the present and of coming generations.

* * * * *

It was just stated that no one concerned in the inquiry was interested in any food product or in any personally profitable business concern, and mention of the Battle Creek Sanitarium, so widely known as the pioneer in fostering the pure food and prepared-cereal manufacture, may cast a doubt upon the matter in the minds of those who do not know that the Sanitarium organisation, in its every department, is a philanthropic, humanitarian institution. It is the parent and feeder of the American Medical Missionary Cause, which already has established branches in something over sixty localities situated in or near large cities in different parts of the world, chiefly America. By perpetual charter all the profits revert to the spread of the work and the employees serve for a mere pittance, deriving their major compensation from enjoyment of the altruistic work.

* * * * *

The old prejudice against the human race which declared that “everybody had an axe to grind,” that there was “a nigger in every woodpile,” and such like slanders, must be modified in the light of recent altruistic development. Altruism has always been existent and had a great new birth with the beginning of our era, but it was never before so frankly put upon a business basis as it is now, and this is fast being applied to every department of business activity. It is now done, not in the name of any particular creed or cult, or for future reward, but because _it pays_--first, last, and all the time.

* * * * *

In the study and pursuit of menticulture the author has found that working for the common good is as necessary to happiness as working for self, and that the retroactivity and reciprocity of the idea multiplies the profits indefinitely.

The sequence of profitable, altruistic interrelation is stated in the “Explanation” of the chain of the A. B. C. Life Series, of which this book is one of the links.

* * * * *

Aside from those actively engaged in the several investigations to whom reference is often made, the author wishes to express special gratitude to Sir Michael Foster and to Professor Henry Pickering Bowditch of the Board of Scientific Assessors. Unselfish and unremitting in their assistance and encouragement, the author’s work has been made easy since their interest was enlisted.

Sir Michael, as Member of Parliament in England, and as a physiological savant, knows that economic nutrition is the key to England’s welfare, as well as the basic necessity of temperance, morality, health, and efficiency, as is expressed in the two documents from him reproduced in the “Report of a Plan for an International Investigation into the Subject of Human Nutrition” and in his “Note” on the Cambridge examination of the author and Dr. Van Someren at Cambridge University laboratories, given herein.

Professor Bowditch, as a distinguished physiologist, publicist, and especially as the President of the Children’s Aid Society, of Boston, Massachusetts, often mentioned as the model institution of its kind in the world, realises that the effort of the author to secure basic knowledge relative to right nutrition, adaptable to kindergarten teaching and home training during the impressionable period of youth, is of the greatest importance in social reform.

A trial suggestion relative to ways and means of _beginning right_ with _all the children_ and thus insuring a regeneration of the classes most in need of reform, in not longer than two decades, is outlined in the author’s appeal for the waifs of society, entitled

“That Last Waif; or Social Quarantine.”

Whenever there is any disposition to slack up in patience or enthusiasm to accomplish the ultimate end aimed at, the picture of the waif in that story is flashed back by memory, and there can be neither forgetfulness, indifference, nor repose until “that last waif” has been given _at least a chance of choosing_ between the right and the wrong, the good and the bad.

POSTINTRODUCTORY

[Just before “going to press” the author has received a letter from his esteemed colleague, Dr. Hubert Higgins, giving the gist of interviews with an eminent European physiologist and with a famous American chemist and dietitian, which so well describes the attitude of the scientific mind towards the problem of human nutrition that the scientific mentor of the writer advises its addition to the book.

By the same post there arrived a letter from Dr. J. H. Kellogg, the life and director of the Battle Creek Sanitarium, expressing practical appreciation, the result of demonstration, of what is being done to solve the problem.

Eliminating the personal element and keeping the ultimate object in view, these communications are coincidentally _a propos_ and intimate to our “Introduction”; hence their reproduction here.

Numerous other letters and extracts from communications received by the writer, bearing upon this subject, from the above and other sympathetic friends are reproduced in “The New Glutton or Epicure,” a free and easy companion of this book, intended to appeal to a variety of readers.

When it is known that the proceeds of all the publications of the author are dedicated to the promotion of the objects they advocate, reference to them or advertisement of them cannot be considered inappropriate.—HORACE FLETCHER.]

EXTRACTS FROM DR. HIGGINS' LETTER

PALAZZINA TASSO, CAMPO S. POLO, VENEZIA.

October 3, 1903.

DEAR MR. FLETCHER,--A. appears to me to have an exceedingly broad and philosophic grasp of the problem of nutrition.

He recognises that all present data are subject to criticism, and that there are no scientifically accurate data available because

(_a_) Observations are taken over too short a period.

(_b_) They have mainly dealt with one side of the problem,--the output of muscular work.

(_c_) The observations are not sufficiently complete.

He acknowledges that cleavage products from food broken down in the intestines by bacteria are the cause of

(_a_) Inefficiency (_b_) Diseases (_c_) Mental derangements. (See Mott’s work.)

He recognises that the majority of people eat far too much. He puts this in the following way. If a “mediæval devil” had wished to discover the most subtle and most effective way to destroy mankind mentally, morally, and physically, he would have arranged for them to be supplied with tasty, well-cooked foods, wines, etc.; in short, he would have used every means to tempt, confuse, and pervert their appetite. He would also have arranged every possible means to prevent their being in the fresh air and taking exercise. He thinks one has here the picture of modern civilisation.

He talked in a very interesting and instructive manner about the necessity and value of exercise and a muscular body for the maintenance of good health. He has evidently worked at and thought a good deal about this side of the subject.

He regrets that there are not more people who realise the huge importance of understanding the nutrition problem for the sake of the progress of humanity. He would like to join all those who are interested in forming an international society, as far as I understood him.

He is most keen on getting subjects, such as myself, for study over a very long period of time,--two to three years,--as he very justly observed “Muscular output is a very small part of the measure of a man’s efficiency. Mental efficiency, manual dexterity, and other psychological tests are necessary.” He seemed very much interested in my idea of making a large number of curves of daily observations. He said that it appeared to him to offer the best means of ultimately measuring the degree of deviation from the subject’s optimum state of health.

He argues the necessity of getting some scientific definition of health.

* * * * *

The phrase that reduces all these people to contemplative silence is this.

“You acknowledge that the state of knowledge is insufficient to prescribe a diet for any individual that he should take daily; or in other words, that there is very little accurate knowledge of the nutrition problem.”

Reply. “Yes. I do not feel I could prescribe a diet for any one with any degree of confidence.”

“Very well, then. Why should not the body have or acquire the quality that all animals have, in a free, natural state, of knowing what their body wants by appetite and taste?”

This is more or less how you put it to me when I first met you at Cambridge. Its full significance did not dawn on me till much later; till, in short, I commenced the study of my desires at Cambridge.

Now this point of view is the rock on which we stand, and is the cause of H.'s and A.'s interest, and as H. said, is the “most fascinating idea” he ever heard.

It had very much the same effect on A. He was reduced to silence. The more you think of it the more you see there is no answer that could contradict it.

He then admits that

(_a_) The food should be finely divided.

(_b_) That it should be thoroughly insalivated.

(_c_) That in all probability most diseases are caused by dietetic error.

(_d_) That we have still to find the optimum health and the optimum diet.

He only kicks at the low proteid. Now I don’t care a “kuss” for the low proteid, as such, or high proteid. Proteid like everything else will be demanded by the appetite when it is wanted.

Our great danger, to my mind, is the tendency so strongly exemplified by some of prescribing diets and quantities and the length of time food should be chewed.[1] Now the very errors we are fighting against are the prescription of methods on insufficient information or knowledge. _You have gone straight back to Nature._ _There is your strength_ in convincing the scientific world, and we must study the problem from that point of view if we are to get any great degree of success.

A. had nothing to say when I told him that I did not hold by either high or low proteid but only by my appetite and taste, developed by ample mouth opportunity to discriminate, which I hoped, in time, to understand more thoroughly than I do now. He told me that he feared that there would be great physical deterioration after a long period of low proteid. I said that I did not believe it would be the case by your method. For instance, right in the midst of a long period of most satisfactory low-proteid supply, I once ate nearly a whole chicken with some ham at Penegal. I could not get saliva for anything else.[2] In short, then, I insisted only on thorough mastication to protect taste and appetite, and had no other theories. I was only concerned in observing the factors determining my taste and appetite. I would be more than contented to leave the question of minimum and maximum quantity of proteid to be settled in the future after normality had been established by practical demonstration.

Yours faithfully, HUBERT HIGGINS.

EXTRACTS FROM DR. KELLOGG’S LETTER

BATTLE CREEK, MICH. October 7, 1903. MR. HORACE FLETCHER.

DEAR FRIEND,--Yours of September 30th just reached my hands and I hasten to reply.

I saw a newspaper note in reference to the soldiers which the government has selected for the dietetic experiments, and also read an interesting article in the _Popular Science Monthly_. You have accomplished a great good thing in enlisting these scientific and military men and interesting them in the investigation of this wonderful reform. The marvellous thing about it is that these busy men of science should have so readily undertaken an investigation which involves so much surrender and self-denial, at least, at the start. I know you are absolutely right. My personal experiences and observations confirm me. In the experiments you mention, which I made in reference to the daily ration for ordinary persons, I simply sought to ascertain, as have others, how much and what kinds of food people are in the habit of using, taking no account of the possible excess or the careless manner in which they eat. The figures I got were sixteen ounces of starch; 1.2 ounces fat, and three ounces proteids,--approximately 2,500 calories. In observation of patients I have seldom found one able to eat this amount. Personally, I habitually eat scarcely half as much. My breakfast to-day was the yolks of two eggs, two or three tablespoonfuls of corn flakes, a moderate-sized potato, and a couple of peaches. At dinner I shall take a little more.

I have been so busy with my patients and the new building, getting things organised, that I have not done as much as I ought to in the way of promoting your splendid reform; but I am going at it now in good earnest. I feel it is one of the greatest things in sight, and it fits right in to all the other things I am trying to do. I feel that I owe you continually a great debt for the efforts you have made and the splendid work you are doing, which will accomplish more for the uplifting of humanity than all that Carnegie and Rockefeller are doing with their millions. What they are doing is mainly to perpetuate old errors, while you are bringing out new truth of basic importance, and a kind Providence has certainly inspired you to do this grand work.

I thank you for all your good thoughts towards us, and assure you the loving encouragement your letters always contain is very much appreciated, and sometimes it gives us a mental uplift just when we need it. The road we are travelling over is not altogether free from thorns. All your suggestions are gratefully received. I remain,

Faithfully yours,

J. H. KELLOGG.

A. B.-Z. PRIMER

EXPLANATION

This is a condensed presentment of a subject of basic importance to everyone, supported by numerous appendices of great scientific weight.

The special object of such brevity and elementary treatment of the subject is:

=1.= To accentuate the facts showing how little we really have to know and do in connection with our sustenance in order to have the NATURAL AUTOMATIC PROCESSES done rightly and healthfully.

=2.= To permit busy persons who will take our dictum as gospel and our advice as sound to learn their necessary share in their own nutrition in the least possible time, leaving the less credulous and more curious to study the appendices at leisure and at will.

=3.= For some ten years it has been the ambition and the aim of the older and non-professional author to embody the fundamental essentials of human responsibility in self-understanding and self-management in not more than ten pages of coarse print that a child could understand and that mothers and teachers might commit to memory and never forget.

This is only a first trial-attempt to fulfil the ambition and the aim; but the appendices show the assembling and concentration of scientific and militant forces which will not allow this subject of primal human interest to remain longer the most neglected of educational departments.

SOME PERTINENT QUESTIONS

Will the reader not ask himself the following questions?

=1.= How much do I know about my own nutrition?

=2.= Do I know the particular need and purpose of my last meal and what it is likely to accomplish?

=3.= Considering my body as an engine, would I accept myself as a competent engineer on my own examination and confession?

=4.= Were I an iron and steel automobile, instead of a flesh and blood automobile, which I really am, could I get a license for myself, as a _chauffeur_, to run myself with safety, based upon my knowledge of my own mechanism and the theory and development of my power?

=5.= Were I an owner of valuable live-stock, would I employ a farm-hand or a stable man, even at so low a wage as fifteen dollars a month, who knew as little about the proper feeding of my animals as I know about the proper feeding of myself and my children?

=6.= Should I employ such an ignorant attendant for my live-stock, and catch him worrying them during their feeding, and hurrying them away from their fodder to hitch them up for work, would I not have the man arrested for cruelty to animals? And yet this is what is habitually done to children!

=7.= Do I appreciate how important it is to learn sufficient of the requirements of economic and healthy nutrition to enable me to escape the depressing and debilitating effects of a faulty nutrition.

=8.= How can I religiously “ask a blessing” upon food and then immediately sin by treating it in a manner abhorrent to the natural requirements?

=9.= If “cleanliness is next to godliness” is it respectable for me to slight my proper feeding in a manner that I know may induce putridity of excreta through indigestion and that _may_ produce fatal disease?

=10.= With All Eternity ahead of me, cannot I afford at least 1■48[3] of my time for careful feeding of my body in a manner known to favour physical health; mental keenness; firmness of character; enjoyable temperance; sexual vigour without morbidity. In fact, general respectability and efficiency?

Having duly reasoned out logical answers to the questions, may they not seem sufficiently important to be remembered and respected as a DIETARY TEN COMMANDMENTS?

A

The Psychology of Nutrition

APPETITE ATTENTION APPRECIATION

APPETITE is the most important factor in digestion (vide Pawlow).

NORMAL APPETITE is indicated by a desire for _some particular_ simple food accompanied by a “watering of the mouth.”

FALSE APPETITE is a general discontent of the body, indefinite of description. It is often expressed by “all gone-ness,” or stomach craving, and calls for _something_, ANYTHING! to smother the discomfort of present or recent indigestion. It is like the thirst which follows a debauch.

IGNORE FALSE APPETITE, and WAIT for a RETURN of NORMAL APPETITE. It will come as soon as body repairs have been effected by natural agencies and more material is required. No one was ever injured by intelligently and calmly waiting for an appetite. No one ever starved to death for lack of appetite. Most human ills come from forcing appetite, anticipating appetite, abuse of appetite in some form.

APPETITE is the most important factor in nutrition. This estimation is based upon evidence given more fully in the various appendices, but the measure of its importance may be briefly stated, as follows:—

First

In its normal state, Appetite is a perfect indicator of the bodily need of nutriment and moisture, both as to quantity and as to the chemical elements required at the moment.

Second

APPETITE is a creature of the mind and does not attach to a tissue. It can be as easily changed, from abnormal to normal, by suggestion, as can the mind itself, and is not like a solid, the form or habit of which has been set in a mould. Whoever has once experienced a bad oyster and has abhorred oysters ever after will substantiate this claim regarding the caprices of appetite.

Third

APPETITE can be easily comprehended and read and the degrees of its satisfaction understood by simple attention and study for a brief period (vide Van Someren).

Fourth

ATTENTION is necessary to create APPRECIATION, and appreciation is absolutely necessary to stimulate the secretion and flow of gastric and other digestive juices (vide Pawlow).

Fifth

ANGER, or shock of any kind, and WORRY, or any of the pessimistic depressants, stop digestive activity and cause indigestion (vide Cannon).

Sixth

MENTICULTURE should begin with its application to selection (through a normalised appetite) of nutriment for the body, and continue to aid digestion by right thinking.

It is very easy to cultivate calm and fortify against surprise, shock, and anger if the nutrition of the body is carefully attended to. The physical and the mental equipments are beautifully reciprocal and necessary to each other in promoting MENTICULTURE.

B

The Mechanical and Chemical Physiology of Nutrition

BUCCAL DIGESTION

THROUGH

MOUTH THOROUGHNESS

Mouth treatment of food, which permits, aids, and includes insalivation (mixing with saliva), and which is both actively digestive in its functions and preparatory to final digestion, is the only _actual mechanical responsibility_ we have in our nutrition; and, in connection with favourable A conditions, insures perfect digestion. It has been so fully and clearly explained in some recent articles, “Observations on Mastication,” by Dr. Harry Campbell, F.R.C.P., physician to the Northwest London Hospital, printed in the “Lancet” of July 11th, 18th, 25th, and August 8th, 1903, that reference to the articles, reprinted herewith, is all that is necessary here.

In giving attention to careful mouth-treatment of soft or liquid foods until they are absorbed by the Swallowing Impulse the best health and economic results are obtained. It should, at least, be tried.

This will not be found to be a tedious operation after a little practice, when the habit of attention and care has been formed. On the contrary, a new appreciation and enjoyment of taste will be acquired, the delight of which has to be experienced to be understood.

Some hints on learning how to _read_ the appetite, _command_ the attention, and _masticate_ and _swallow_ food material _properly_ follow.

METHOD

First; Last; and All the Time

Be sure that you are really hungry and are not pampering False Appetite. If true appetite that will relish plain bread alone is not present, wait for it. Especially beware of the early-morning habit-craving. Wait for an _earned_ appetite, if you have to wait till noon. Then: “Chew,” “Masticate,” “Munch,” “Bite,” “Taste” everything you take in your mouth (except water, _which has no taste_), until it is not only thoroughly liquefied and made neutral or alkaline by saliva, but until the reduced substance all settles back in the (glosso-epiglottidean) folds at the back of the mouth and excites the Swallowing Impulse into a strong inclination to swallow. Then swallow what has collected and has excited the impulse, and continue to chew _at_ the remainder, liquid though it be, until the last morsel disappears in response to the Swallowing Impulse. Never forcibly swallow anything that the instincts connected with the mouth show any disposition to reject. It is safer to get rid of it beforehand than to risk putting it into the stomach.

Sip and taste milk and all liquids that have taste as the wine-tasters do. They never drink wine and yet they get all the enjoyment there is in it and waste none. In a very short time sipping and tasting liquids and masticating and tasting solid food for “all they are worth” will become an agreeable and profitable fixed habit.

WHETHER WE “EAT TO LIVE OR LIVE TO EAT,” WHY NOT DO AS ABOVE?

Z

The True Chemical End-Point of Digestion

THE DIGESTION-ASH WHAT IT SHOULD BE LIKE WHEN IT IS NORMAL

First

In adults; or, in children after the eruption of teeth and the ingestion of solid food: The non-liquid and non-gaseous waste of the human body, which, in its normal state, is not offensive, should be very small, in quantity, should be pillular in form, either separate or massed together; should have no odour when released, should take on no odour on standing, should be entirely aseptic (non-poisonous); should drop freely from the exit, leaving nothing behind to wash or wipe away. It _may_ not be collected in the intestines of full-grown and elderly persons, when normal, as above, in sufficient quantity to require or necessitate emptying oftener than from twice a week to once in two weeks; according to age, activity, etc.; and should neither invite nor justify the description “it is not that which goeth into a man that defileth him but that which cometh out.”

Second

Economic Digestion-Ash (solid _excreta_), as a daily average for an adult of 140 lbs. (10 stone; 63.5 kilos), including moisture, when released, should not weigh more than two ounces (56.70 grams). An average of less than one half this amount of waste has been secured in test experiments.

Third

The true test of healthy Z is absence of odour and completeness, ease and cleanliness of delivery. Frequency or otherwise, does not so much matter. Quantity too, is not so important; but with foul odour there is disturbance, strain and danger.

The normal man is a cleanly being with all excreta inoffensive; and by these tokens he may be his own private judge.

Why is it that barn-yards are tolerable to the human senses while open _dépôts_ of human excreta are fever-breeding nuisances and intolerable to beasts and humans alike?

This curse of putrid excreta caused more deaths from enteric fever during the Boer War in South Africa than all other causes. It is equally a menace to health and even to life while being formed and carried in the body.

Fourth

Offensive excreta are quite certain evidence of neglect of the self-controllable parts of our own nutrition. They are the tell-tale condemnation of ignorance or carelessness. Each person should learn to read the true bulletins of his health conditions in his waste-products of digestion.

Z

is the form the body _must_ assume to render emptying of the digestion-ash natural and easy. Man was built to squat on his heels in defecating, and sitting erect on a modern seat is like trying to force a semi-solid through a kinked hose. HEALTHY HUMAN EXCRETA ARE NO MORE OFFENSIVE THAN MOIST CLAY AND HAVE NO MORE ODOUR THAN A HOT BISCUIT.

A. B.-Z. FIGURE

TO ILLUSTRATE THE “DIVISION OF LABOUR”

First. A

Psychic Environment } This Mental State } involves:

APPETITE (to select for) } ATTENTION (to prepare for) } DIGESTION APPRECIATION (to assist in) }

(Absolutely necessary to secure secretion and flow of the digestive juices: Vide Pawlow and Cannon.)

Second. B

BUCCAL-DIGESTION } This MOUTH-TREATMENT } involves:

MECHANICAL (teeth) } THOROUGHNESS CHEMICAL (salival) }

(Absolutely necessary to secure complete digestion and avoid the putridity incident to bacterial decomposition: Vide Campbell and Van Someren.)

INTERMEDIATE

The twenty-three letters between “=B=” and “=Z=” represent but an inadequate proportion for the spelling of the enormous share Nature assumes in our welfare, marvellously performing her forty-seven forty-eighths share in the secret laboratory of the alimentary canal.

Third. Z

The true chemical end-point of digestion, by which each self-respecter may know how well he has respected his “A” and his “B,” and how faithfully he has performed his one forty-eighth share in the promotion of his own most fundamental interest.

PREFACE TO 1906 EDITIONS

Since the former introductions were written much success has been attained in further advancing the reforms advocated in the _A. B. C. Life Series_. Professor Chittenden has published his report on the Yale experiments in book form in both America[4] and England,[5] and his results have been accepted in scientific circles the world over as authoritatively conclusive.

At the present writing the most important Health Boards of Europe[6] are planning to put the new standards of dietary economy into practical use among public charges in a manner that can only result in benefit to the wards of the nations as well as make an important saving to the tax-payers. In the most important of these foreign public health departments the Health Officer of the Board has himself practised the newly established economy for two years, and his plans are formulated on personal experience which fully confirms Professor Chittenden’s report and that of the author as herein related.

At a missionary agricultural college, situated near Nashville, Tenn., where the students earn their tuition and their board while pursuing their studies, a six months' test of what is termed “Fletcherism” resulted in a saving of about one half of the drafts on the commissary, immunity from illness, increased energy, strength and endurance, and general adoption of the suggestions published in the several books of the author included in the _A. B. C. Life Series_.

In the various departments and branches of the Battle Creek Sanitarium in America, and widely scattered over the world, some eight hundred employees and thousands of patients have been accumulating evidence of the efficacy of “Fletcherism” for more than three years, and scarce a month passes without a letter from Dr. Kellogg to the author containing new testimony confirming the _A. B. C._ selections and suggestions.

The author has received within the past two years more than a thousand letters bearing the approval of the writers with report of benefits received which seem almost miraculous, and these include the leaders in many branches of human occupation--physiologists, surgeons, medical practitioners, artists, business men, literary workers, athletes, working men and women, and almost every degree of mental and physical activity.

One of the medical advisers of King Edward, of whom the King once said: “He is a splendid doctor but a poor courtier,” follows the suggestions of these books in prescribing to his sumptuous clients.

HISTORY OF DEVELOPMENT

AND

SUPPORTING EVIDENCE

SUMMARY OF THE FOREGOING PAGES BY AN EXPERIMENTER OF ONE MONTH’S EXPERIENCE

(_Requested and given as a test of effectiveness_)

The entire principle of economic nutrition is simple and practical. It does not prescribe that we shall follow any special diet nor do away with any of our meals. It simply requires you to throw present habits and conventions to the winds, and for a little time try the experiment of giving the matter of your every-day living honest, intelligent thought.

Eat all you crave, but do not eat more than this simply because you have been in the habit of doing so. See to it that each morsel put into your mouth is thoroughly masticated and mixed with the saliva before going down into the stomach, which is not equipped to perform the work which the teeth and salivary glands were given you for. The stomach will struggle bravely to overcome the abuse which you heap upon it, but in spite of all it can do to manage hastily chewed food, undigested portions remain which clog the intestines and interfere with the healthy conditions which Nature intended.

The appetite is given as an indicator of what the body requires. If you crave potato, the system needs starch, which the saliva makes digestible, but which the acids of the stomach cannot dissolve. Other needs of the system are similarly indicated. Take the trouble of asking your appetite the question, instead of accepting the conventional number of courses simply because they are set before you. The appetite will close the valve when you have eaten enough, if you will give it a chance.

Suppose your time for eating is limited; in twenty minutes you could not eat slowly the luncheon which you usually select. Then eat that much less. The amount of food which you can eat and thoroughly masticate in twenty minutes will give you more nourishment and will sustain you better than twice the amount thrown into the stomach in the same manner in which a man usually packs a trunk.

Why is it that so many men require a “bracer” at eleven o’clock? Because they have loaded their stomachs with a heavy breakfast, and instead of gaining nourishment from it, the smothered organ is doing its best to tear the undigested morsels to pieces, that they may pass into the intestines and prevent sickness, or even death. The time finally arrives when it finds itself unable to do this, and then comes acute indigestion, or something worse, and the system becomes run down, ready to receive typhoid, or any other germs which happen to come along.

Do you know why griddle-cakes hurt you? Because the syrup, which is cane-sugar,--and as such is indigestible,--is allowed to pass through the mouth and down into the stomach, without being properly mixed with the saliva, which makes it digestible. As soon as it enters the stomach it becomes acid and interferes with everything it meets. Had the cakes been properly masticated and mixed with the saliva, the cane-sugar would have become grape-sugar, and in this form it is easily digested.

Why is it that stout people are advised to avoid starchy foods? Economic nutrition does not advise this. Potatoes, eaten too hastily, when not craved by the appetite, supply the system with a superabundance of starch, and this is fat-inducing. Potatoes are supposed to produce fat; but if your appetite craves potato, and you properly masticate it, eating only as much of it as satisfies your appetite, the system absorbs it all, leaving nothing to produce fat. On this same principle economic nutrition assures that the same food, taken in accordance with its requirements, will add to one man’s weight and decrease another’s, simply because proper care of the stomach supplies the vital organs with the necessary materials to form each individual person after the model which Nature intended for him. If Nature intended him to be slight, economic nutrition will not make him heavy; if Nature intended him to be

muscularly strong and heavy, economic nutrition will not reduce his weight. In each case he will enjoy that perfect condition which Nature intended him to possess without fat encumbrance.

Did you ever try to reason out why it is necessary for athletes to go into training? Simply because, in order to get the best use of their strength, they are obliged to spend some number of weeks or months in overcoming false conditions which they have brought upon themselves. Any person who lives in accordance with the simple requirements of economic nutrition has nothing of this kind to overcome, but is in perfect condition all the time.

The requirements of economic nutrition are not hardships but pleasures. Proper mastication and insalivation (mixing with saliva), give your sense of taste far greater gastronomic enjoyment than you have ever before had. If you are a wine drinker, try insalivating a little port wine; but it must be good wine, for this is a severe test. A sip will quench your immediate desire and give you more pleasure than a whole glass gulped down. The professional tea-taster does this in tasting tea; he never allows himself to drink any tea at all, for drinking anything that has taste destroys the delicacy of the sense of taste. But he will tell you that he gets more real enjoyment out of the little he takes than he previously gained from drinking a larger amount. The same thing applies to the professional wine-tasters; they never drink any wine, and yet they enjoy the taste of wine as drinkers never can do. These men adopt this method as a business; is their commercial advantage of greater importance than your health and happiness, and even life itself?

Is it not ridiculous that the average man is so ignorant of the engine which supplies him with all his activity and upon which depends every action of his life? Could you tell, were you asked, the particular need and purpose of your last meal and what it is likely to accomplish? Consider your body as an engine: would you accept yourself as a competent engineer on your own examination and confession? Would you employ a chauffeur to run your automobile who knew as little about its mechanism and requirements as you do about your own stomach? Yet which is of greater importance? Were you the owner of valuable live-stock, would you dare entrust their care to a farm-hand or stableman who knew as little about their proper feeding as you know about your own proper feeding or that of your children?

Have you ever stopped to think why the excrements are foul and odorous? Simply because undigested food, which should have been so masticated as to give the body nourishment, is thrown off by the stomach into the intestines, there to decay and produce this unclean condition. If the dead carcass of a cow is lying in the road, it is removed before it has an opportunity to decay and thus become filthy and dangerous. Yet how much more safe it would be for the carcass to lie where it was than for you to take portions of it into your intestines and allow it to decay there instead of in the road? In other words, food is intended to be eaten that nourishment may be gained from it, and when you only gain a part of the nourishment, you prostitute your stomach and take tremendous risks of germ diseases in your body.

These facts are set forward thus simply in the hope that they may impress the reader as they have impressed the writer. Economic nutrition is not a joke, is not a fad; it is solely an appeal to self-examination and self-instruction in the most vital question of all the world, since upon perfect nutrition depends not only health, but strength, mental acuteness, moral tendencies, attractability to others, happiness, and, in fact, life itself.

FIRST SCIENTIFIC RECOGNITION OF THE PRINCIPLES OF ECONOMIC NUTRITION OUTLINED IN “GLUTTON OR EPICURE”

[With the exception of a brief review of _Glutton or Epicure_, by Dr. Joseph Blumfield, of London, published in _The Lancet_, no scientific or professional recognition of the principles of an economic nutrition attained by means of thorough buccal digestion was gained until issue of the following paper by Dr. Ernest Van Someren, of Venice, Italy.

The previous autumn and winter had been devoted to experiments by Dr. Van Someren and the writer, in co-operation with Dr. Professor Leonardi, for twelve years Professor of Chemistry in the University of Pavia, Italy. In the spring and summer of 1901 the field of experiments was changed to Mendel Pass, _bei_ Bozen, Süd Tirol, Austria, and related to endurance work in climbing mountains and bicycle runs among the Dolomites.

Dr. Van Someren’s paper attracted the attention of Sir Michael Foster, Professor of Physiology at the University of Cambridge, England, and Permanent Honorary President of the International Congress of Physiologists.

Professor Foster entered into correspondence with Dr. Van Someren, and this was followed by an invitation to Dr. Van Someren and the writer to attend the Congress which was to convene in Turin, Italy, during the month of September following. At the Congress Dr. Van Someren presented a technical thesis on the probable causes of the economy attained, and gave a demonstration of the movement of his Swallowing Reflex in relation to food in the process of liquefaction and preliminary digestion in the mouth.

Following the Congress we received an invitation to visit Cambridge, England, and submit to tests of nitrogenous measurements in the Physiological Laboratory of the University, under the direction of Dr. F. Gowland Hopkins; and also to an examination of the bacterial flora incident to the nitrogenous estimations, under the direction of Dr. George H. F. Nuttall.

The report of the experiments in the Chemical-Physiological Department is given in the “NOTE” of Sir Michael Foster, which follows Dr. Van Someren’s paper, but the bacterial examination was not carried far enough to warrant a scientific report, owing to difficulty of obtaining, at the time, sufficient data.—HORACE FLETCHER.]

WAS LUIGI CORNARO RIGHT?

A PAPER READ BEFORE THE PHYSIOLOGICAL SECTION OF THE BRITISH MEDICAL ASSOCIATION, AUGUST, 1901, BY ERNEST VAN SOMEREN

Mr. President and Gentlemen:

Being a general practitioner, it is with some trepidation and an apology that I present myself before this section. The reasons for my doing so are: First, that I believe that a hitherto unsuspected reflex in deglutition has come to light which has an important bearing on health, the prevention of disease and on metabolism. Second, that any theory whatever, based on a possible physiological function, claiming to diminish, as this does, the amount of sickness and suffering now existent, should have serious investigation. Third, that I desire to enlist your skilled help in the consideration of the theories I have doubtless crudely erected on my premise.

According to the “Encyclopædia Britannica,” “Luigi Cornaro (1467-1566) was a Venetian nobleman, famous for his treatises on a temperate life. From some dishonesty on the part of his relatives, he was deprived of his rank and induced to retire to Padua, where he acquired the experience in regard to food and regimen which he has detailed in his work. In his youth he lived freely, but after a severe illness at the age of forty, he began under medical advice gradually to reduce his diet. For some time he restricted himself to a daily allowance of 12 ozs. of solid food and 14 ozs. of wine. Later in life he still farther reduced his bill of fare, and he found that he could support his life and strength with no more solid meat than an egg a day. So much habituated did he become to this simple diet that when he was about seventy years of age the addition, by way of experiment, of 2 ozs. a day had nearly proved fatal. At the age of eighty-three he wrote his treatise on the ‘Sure and Certain Method of Attaining a Long and Healthful Life.’ And this work was followed by three others on the same subject, composed at the ages of eighty-six, ninety-one, and ninety-five, respectively. ‘They are written,’ says Addison (‘Spectator,’ No. 195), ‘with such a spirit of cheerfulness, religion, and good sense, as are the natural concomitants of temperance and sobriety.’ He died at the age of ninety-eight. Some say of 103!

Now, was Luigi Cornaro right? Did he make use of a physiological process unknown to us of the value of which he was not cognisant? To live to an advanced age, must we be as temperate as he, reducing the quantity of our food to a minimum required by Nature?

That we all eat more than we can assimilate is unquestionable. How can we determine the right quantity? Instinct _should_ guide us, but an abnormal appetite often leads us astray. Nature’s plans are perfect if her laws are obeyed. Disease follows disobedience. Wherein do we disobey?

We live _not_ upon what we eat, but upon what we digest; then why should undigested food, recognisable as such, be deemed a normal constituent of our solid egesta?

Something like the following must be a common experience to general practitioners, especially to those practising on the Continent. The patient comes to see us and volunteers the information that he or she has the “gout,” “rheumatic gout,” or “dyspepsia.” Symptoms are asked for. The case is gone into carefully for causation. An appropriate diet and an appropriate bottle of medicine prescribed. As the patient leaves the room, we may, or may not, call attention to the fact that both teeth and saliva are meant to be used. The patient returns, better, _in statu quo_, or worse. If better, he remains so while under treatment, and relapses when he returns to ordinary habits. If unaffected, or worse, we try again and again, until we despair, then take or send him to a consultant.

Temporary benefit, possibly owing to renewed hope, results; but finally the unfortunate gets used to his sufferings and, if he can afford it, is sent to join the innumerable hosts that wander from one _Bad_ to another, all Europe over, trying, praising, and damning each in turn. Their manner of living is, of course, at fault. Nature never intended that man should be perpetually on a special diet and hugging a bottle of medicine, nor did she ordain that he should go wandering over the map of Europe drinking purgative and other waters.

Though early yet to speak with certain voice, it would seem that we are provided with a Guard, reliance on which protects us from the results of mal-nutrition. There seems to be placed in the fauces and the back of the mouth a Monitor to warn us what we ought to swallow and when we ought to swallow it. The good offices of this Monitor we have suppressed by habits of too rapid eating, acquired in infancy or youth.

Last November my attention was called by Mr. Horace Fletcher, an American author living in Venice, to the discovery in himself of a curious inability to swallow, and a closing of the throat against food, unless it had been completely masticated. My informant stated that he noticed this peculiarity after he had begun to excessively insalivate his food, both liquid and solid, until all its original taste had been removed from it. Any tasteless residue in the mouth, being refused by the fauces, required a _forced_ muscular effort to swallow. He further told me that since adopting this method of eating he had been cured of two maladies, adjudged chronic, the suffering from which rendered him ineligible for Life Insurance. His weight now became reduced from 205 lbs. to 165 lbs. He had practised no abstemiousness, had indulged his appetite, both as to selection and to quantity, without restraint, and for the last three years had enjoyed perfect health.

After his cure, he was accepted without difficulty for insurance, the last examination finding him an unusually healthy subject for his age. Having leisure, he had spent three years in investigating the cause of his cure, had pursued experiments upon others, and had extended his inquiries, both in America and Europe, until our meeting in Venice. He had also published a statement and inquiry in book form, entitled “Glutton or Epicure,” which had been reviewed by the “Lancet.”

For nearly a year I also had been experimenting on myself and others with various diets, and was ready to believe that in the _manner_ of taking food and not altogether in its varying _matter_ lay perhaps its protean effects on our system. I at once adopted the same method of eating. At the end of six weeks, I noticed that not only did the fauces refuse to allow of the passage of imperfectly prepared food, but that such food was returned from the back to the front of the mouth by an involuntary, though eventually controllable, muscular effort taking place in the reverse direction to that occurring at the inception of deglutition.

What actually happens is this: Food, as it is masticated, slowly passes to the back of the mouth, and collects in the glosso-epiglottidean folds, where it remains in contact with the mucous membrane containing the sensory end-organs of taste. If it be properly reduced by the saliva it is allowed to pass the fauces,--a truly involuntary act of deglutition occurring. Let the food, however, be too rapidly passed back to these folds, _i.e._, before complete reduction takes place, and the reflex muscular movement above referred to occurs. The process of this reflex is as follows: The tip of the tongue is involuntarily fixed at the backs and bases of the lower central incisor teeth by the anterior fibres of the geniohyoglossi muscles. With this fixed point as fulcrum, the lower and middle fibres of these muscles, aided by those of the stylohyoid and styloglossi muscles raise the hyoid bone, straighten out the glosso-epiglottidean folds, passing their contents forward, by the fauces, the opening of which is closed by approximation of its pillars and contraction of the superior constrictor. The tongue, arched postero-anteriorly by the geniohyoglossi, palato, and styloglossi muscles, laterally, by its own intrinsic muscles, is approximated to the fauces, soft and hard palates in turn, and thus, the late contents of the glosso-epiglottidean folds are returned to the front of the mouth for further reduction by the saliva preparatory to deglutition.

The word reduction is used for the reason that all foods tested, without exception, give an acid reaction to litmus, when served at table. The reflex muscular movement occurs in the writer’s case from five to ten times during the mastication of each mouthful of food, according to its quantity and its degree of sapidity. As often as it recurs, the returned food continues to give an acid reaction, while food allowed to pass the fauces is alkaline.

Saliva, flowing in response to the stimulation of taste, seems more alkaline than that secreted in answer to mechanical tasteless stimulation. It is found that the removal of original taste from any given bolus of food coincides with cessation of salivary flow and complete alkaline reduction. The fibre of meat, gristle, connective tissue, the husk of coarse bread and cellulose of vegetables are carefully separated by the tongue and buccal muscles and rejected by the fauces. To swallow any of these necessitates a _forced_ muscular effort, which is abnormal.

Adult man was not originally intended to take his nourishment in a liquid form, consequently all liquids having taste, such as soup, milk, tea, coffee, cocoa, and the various forms of alcohol, must be treated as sapid solids and insalivated by holding them in the mouth, moving the tongue gently, with straight up and down masticatory movements, until their taste be removed. Water, not having taste, needs no insalivation and is readily accepted by the fauces.

In explanation of the phenomenon described, the following theory is advanced: The fauces, back of the tongue, epiglottis, in short, those mucous surfaces in which are placed the sensory end-organs of taste and “taste-buds” (the distribution of which, by the way, has yet to be explained), that these surfaces, readily becoming accustomed to an alkaline contact by excessive insalivation and consequent complete alkaline reduction of the food, afterwards resent an acid contact and express their resentment by throwing off the cause of offence by the muscles underlying them.

This phenomenon must not be confused with the cases of rumination and regurgitation, which from time to time are recorded. The food in this case is not swallowed, nor does it pass any point from which it can be regurgitated. Eighty-one individuals of different nationalities and from several classes of society whom we have studied are now in conscious possession of their reflexes. These seem readily educated back to normal functions by all who seriously and patiently adopt the habit of what seems only at first to be excessive insalivation.

The dictum “bite your food well” that we so often use, has no meaning to those suffering from the results of mal-assimilation and mal-nutrition, especially should they have few or no teeth of their own. I make so bold as to state that dyspepsia _et morbi hujus generis omnis_ will cease to exist if patients be persuaded to bite their food until its original taste disappears, and it is carried away by involuntary deglutition.

The important point of the whole question seems to be this alkaline reduction of acid food before it passes on to meet subsequent digestive processes elsewhere, which then become alternately acid and alkaline.

In the first few months of infant life, when saliva is not secreted, Nature ordains that mammary secretion be alkaline. With the eruption of teeth come an abundant flow of saliva and a synchronous infantile capacity for managing other foods. This flow of saliva depends on a thorough demand and use to maintain its generous supply. It is just at this time that children learn to bolt their food,--the demand fails, with a consequent detriment to the salivary glands, digestive processes, and the system generally.

A, B, C, and D were placed on an absolute milk diet. A drank his milk in the ordinary way, and at the end of three days begged to discontinue the experiment owing to disgust at the monotony of the diet. B, C, and D continued the experiment for seventeen days, insalivating the milk, but to a varying extent, B the least and D the most. Though D took most milk, he excreted least solid egesta, C excreting less than B. Can one infer that increased insalivation of a non-starchy food insured its better digestion and assimilation? Each subject took as much milk only as his appetite demanded, D taking the most, which never exceeded two litres daily. The weights of the subjects after the usual sudden drop of the first three days remained remarkably even until the end of the experiment. B, C, and D all relished the diet, and it satisfied the requirements of their appetites, but they experienced an increasing monotony.

As long ago as the seventeenth century, before the transformation of matter into energy by the animal organism, known as Metabolism, was understood, the fact was recognised that by the lungs, kidneys, skin, and intestines, substances no longer useful to the organism were eliminated, the retention of which proved harmful. The nature of these substances was unknown, but it was noted that however much the food was increased the weight of the body remained the same. In other words, a state of complete nutritive equilibrium was maintained.

The following table contains the _résumé_ of two experiments in which a state of complete nutritive equilibrium was maintained by individuals of about the same weight, on widely different quantities of food similar in quality. The subjects of the experiments were a laboratory assistant of Dr. Snyder, of the U. S. Department of Agriculture, and the writer. The experiment of the former was made primarily to show the relative digestibility of the several articles of diet, potatoes, eggs, milk, and cream:

■■■

411.08 grammes ■ 124.7 grammes Milk (daily average) ■ 710 c.c. ■ 710 c.c. Cream (daily average) ■ 237 c.c. ■ 237 c.c. Daily urine ■ 1108 grammes ■ 1098 grammes Daily fæces ■ 204 grammes ■ 18.9 grammes ——————————————

What has just been stated is based not entirely on experimental evidence but somewhat upon inference. The inference seems justified because the excreta, more especially of the intestines, but also of the kidneys and skin, become almost odourless and entirely inoffensive. The solid egesta are voided thickly covered with mucus, leaving the end of the bowel dry and clean. The sense of cleanliness can only then be appreciated to the full, for it is internal as well external. _Flatus_ is no longer produced. The urine is inoffensive and seems to be materially changed in quality, as shown by chemical analysis. Uric acid, the chlorides, and, more markedly, aromatic sulphates are reduced in quantity.

Owing to deliberation in eating, necessitated by this new habit, satiety occurs on the ingestion of considerably less food. By carefully studying one's self I believe it possible to cultivate an instinct which will regulate not only the quantity but the quality of food that the body may need, and that in the _normal health_ of a full-grown body, no more food either in quantity or quality should be supplied than suffices to supply diurnal waste. Any excess must result in pathological processes.

Although there results enhanced pleasure in the taking of all foods, rich and simple, and especially in the appreciation of good wines, the quantities of these foods and beverages that suffice to fully satisfy the appetite are much smaller than before, while there is a marked preference for the simpler kinds of food. The writer now can imagine no more pleasurable meal than one consisting of good brown bread, eggs, butter, cheese, and cream. These, with fresh vegetables and a very little fruit, form his staple diet. This tendency and preference for simple foods is the general experience among those who have recovered their reflexes of deglutition.

Following on the ingestion of a lessened quantity of food and on its better assimilation, there is less waste, the egesta are voided less frequently, sometimes only once in five to eight days.

The lower bowel is not the reservoir it formerly was. So hæmorrhoids cease from troubling and constipation cannot exist. For this same reason the body, at the beginning of the practice, commences to approximate to its normal weight, increasing or decreasing as the individual's environment demands.

A few more words only need be said. It has been easy to state the results of experiments and observations: but the acquiring of this new reflex, while pursuing daily occupations, is not easy, and needs more than a little patience and much serious thought. The habits of a lifetime cannot be changed in a few days or weeks. The shortest time in which the reflex has been re-established is four weeks, and this only by avoiding conversation at meal-time and concentrating the attention on keeping the food in the mouth until complete alkaline reduction has taken place and sapidity has disappeared.

In closing I wish to maintain as a fact, gentlemen, of the truth of which you will only be convinced by actual experience, that by the restoration of this reflex and in complete dependence on its use, there lies true health, the establishment of a condition of stable nutrition and the possible abrogation of two great predisposing factors of disease, mal-assimilation and mal-nutrition. Unless there be among you, as in the "Cities of the Plain," a parlous minority who possess this reflex and take your food as you ought, none of you are in the enjoyment of such health as you might have. A like punishment will be meted out to you as was visited on those cities, for you will all be consumed long before your day by the unnecessary combustion in your bodies caused by the circulation in them of toxins, the product of undigested and decomposing food.

The writer, bearing in mind the warning suggested by the Frenchman whose donkey died as soon as he had reduced his food to a single wisp of straw, finds that he is taking less and less food. While his mind is open as to his arriving at the final diet of Luigi Cornaro, yet it is easily conceivable that living a similar life of retirement in a placid environment, it would be quite possible to do as he did. Hence the title of this paper and the queries at the commencement.

The objects in publishing and distributing this paper are twofold: to make the subject as widely known as possible, and to solicit the aid of colleagues in investigating it more fully.

There is ready at the service of the general practitioner an important and potential therapeutic agent in the saliva of his patients and in the use _ad finem_ of their salivary digestions.

By any chance should readers of this paper wish to ask any questions, the writer will be happy to communicate with them.

183, CALLE DEL CAPELLO NERO, Piazza San Marco, Venice, Italy.

Editor's notes. (1) Confirmatory evidence of the correctness of the deductions made in this paper has begun to come in from many professional sources and notably from a famous child specialist who avers that children would follow the natural requirements in eating were it not for artificial food, bad example, and bad teaching.

(2) In a report of a paper read before the _Société de Biologie_, Paris, France, March 15th, 1902, by M. Max Marckwald, of Kreuznach, “ON DIGESTION OF MILK IN THE STOMACH OF FULL-GROWN DOGS,” the following appears: “Hence these experiments confirm those of Horace Fletcher and Ernest H. Van Someren on the importance of prolonged mastication” (_translation_). Referring, as the latter statement does, to mastication (insalivation) of liquid, it gives an important suggestion relative to some probable causes of uncertain or defective digestion in human nutrition.

THE CAMBRIDGE TESTS

[In connection with a report of the Cambridge Examination the writer wishes to acknowledge the interest and assistance of Dr. Francis Gowland Hopkins, head of the Physiological-Chemical Department of the Physiological Laboratory of the University; Dr. George H. F. Nuttall, in charge of the Bacteriological Section of the Pathological Laboratory; Mr. Sidney W. Cole, Mr. Robert Barrett, and Dr. Hubert Higgins, both for practical work in the laboratory and in serving as test-subjects. To Dr. Higgins so much is due that it is difficult to measure. Since our first meeting in Cambridge, Dr. Higgins has been unremitting in his study of the subject and in consideration of its application to human betterment. Having the altruistic temperament inborn and not yet smothered by disappointment, the good doctor has consecrated himself to the service of poorer humanity, and his inspiration in so good a cause is wonderful motive power behind the native desire to do good. The statement of Dr. Higgins' experiences in pursuit of an Economic Nutrition is given in his own manner in the new edition of _Glutton or Epicure_, which is being published coincidently with this volume in the A. B. C. Life Series.

At the time we were in Cambridge, Dr. Hopkins and Mr. Cole had just published their paper in the _Journal of Physiology_ (English), describing their isolation of the tryptophane element of the proteid molecule which had eluded chemists from the beginning. In tryptophane they found embodied the odourous indol and skatol which appear so offensively in the putrid decomposition of proteid. In the excreta of the test-subjects in our Economic-Nutrition-Inquiry these malodorous substances did not appear, and hence another question is opened up to investigation relative to the putridity of human excrement under ordinary conditions of carelessness, and the absence of putridity in the case of nutrition accomplished by aid of thorough buccal treatment of food preparatory to digestion.

It is a matter of interest, relative to the patience required in science, to state that Dr. Hopkins and Mr. Cole were fourteen months searching for the fugitive tryptophane element after they received their first clew to its whereabouts. When isolated, tryptophane masses in a substance having the appearance of silver, but not the solidity of that metal.—HORACE FLETCHER.]

EXPERIMENTS UPON HUMAN NUTRITION

NOTE BY SIR MICHAEL FOSTER, K.C.B., M.P., F.R.S.

In 1901 Dr. Ernest Van Someren submitted to the British Medical Association, and afterwards to the Congress of Physiologists at Turin, an account of some experiments initiated by Mr. Horace Fletcher. These experiments went to show that the processes of bodily nutrition are very profoundly affected by the preliminary treatment of the food-stuffs in the mouth, and indicated that great advantages follow from the adoption of certain methods in eating. The essentials of these special methods, stated briefly and without regard to certain important theoretical considerations discussed by Dr. Van Someren, consist of a specially prolonged mastication which is necessarily associated with an insalivation of the food-stuffs much more thorough than is obtained with ordinary habits.

The results brought to light by the preliminary experimental trials went to show that such treatment of the food has a most important effect upon the economy of the body, involving, in the first place, a very notable reduction in the amount of food--and especially of proteid food--necessary to maintain complete efficiency.

In the second place this treatment produced, in the experience of its originators, an increase in the subjective and objective well-being of those who practise it, and, as they believe, in their power of resistance to the inroads of disease. These secondary effects may indeed be almost assumed as a corollary of the first mentioned; because there can be little doubt that the ingestion of food--and perhaps especially of proteid food--in excess of what is, under the best conditions, sufficient for maintenance and activity, can only be deleterious to the organism, clogging it with waste products which may at times be of a directly toxic nature.

In the autumn of 1901 Mr. Fletcher and Dr. Van Someren came to Cambridge with the intention of having the matter more closely inquired into, with the assistance of physiological experts. The matter evoked considerable interest in Cambridge, and observations were made not only upon those more immediately interested, but upon other individuals, some of whom were themselves medical men and trained observers.

Certain facts were established by these observations, which, however, are to be looked upon as still of a preliminary nature. The adoption of the habit of thorough insalivation of the food was found in a consensus of opinion to have an immediate and very striking effect upon appetite, making this more discriminating, and leading to the choice of a simple dietary, and in particular reducing the craving for flesh food. The appetite, too, is beyond all question fully satisfied with a dietary considerably less in amount than with ordinary habits is demanded.

Numerical data were obtained in several cases, but it is not proposed to deal with these in detail here, as they need the supplementary study which will be shortly referred to.

In two individuals who pushed the method to its limits it was found that complete bodily efficiency was maintained for some weeks upon a dietary which had a total energy value of less than one-half of that usually taken, and comprised little more than one-third of the proteid consumed by the average man.

It may be doubted if continued efficiency could be maintained with such low values as these, and very prolonged observations would be necessary to establish the facts. But all subjects of the experiments who applied the principles intelligently agreed in finding a very marked reduction in their needs, and experienced an increase in their sense of well-being and an increase in their working powers.

One fact, fully confirmed by the Cambridge observations, consists in the effect of the special habits described upon the waste products of the bowel. These are greatly reduced in amount, as might be expected; but they are also markedly changed in character, becoming odourless and inoffensive, and assuming a condition which suggests that the intestine is in a healthier and more aseptic condition than is the case under ordinary circumstances.

Although the experiments hitherto made are, as already stated, only preliminary in nature and limited in scope, they establish beyond all question that a full and careful study of the matter is urgently called for.

For this fuller study the Cambridge laboratories do not possess at present either the necessary equipment or the funds to provide it. For the detailed study of the physical efficiency of a man under varying conditions, elaborate and expensive apparatus is required; and the advantages claimed for the special treatment of the food just discussed can only be fully tested by prolonged and laborious experiments calling for a considerable staff of workers.

It is of great importance that the mind of the lay public should be disabused of the idea that medical science is possessed of final information concerning questions of nutrition. This is very far indeed from being the case. Human nutrition involves highly complex factors, and the scientific basis for our knowledge of the subject is but small; where questions of diet are concerned, medical teaching, no less than popular practice, is to a great extent based upon empiricism.

But the scientific and social importance of the question is clearly immense, and it is greatly to be desired that its study should be encouraged.

M. FOSTER.

April 26th, 1902.

REPORT OF A PLAN FOR THE INSTITUTION OF AN INTERNATIONAL INQUIRY INTO THE SUBJECT OF HUMAN NUTRITION

[Sir Michael Foster's "Note" (preceding) and Professor Chittenden's article in the _Popular Science Monthly_ (following), which form a part of this book, show a common want of exact knowledge relative to human nutrition not at all creditable to human intelligence at the beginning of the twentieth century; but they both offer hope of relief from this discreditable stigma in systematic study of the question. For this purpose an international inquiry was proposed, a plan was drawn up under advice of Sir Michael Foster, and the matter was given to the writer to promote by the best means available.

The Carnegie Institution seemed, at the time, the most likely supporter of such a scheme; but owing to an embarrassment of applications for support of American science needs, it was considered best not to attempt any foreign or even international benefaction, for the present at least, and hence other means of furthering the inquiry were sought.

The invitation of Professor Chittenden to repeat the demonstration of food-economy made by the author and Dr. Van Someren at Cambridge, England, of which Sir Michael Foster's "Note" treats, at the laboratories of the Sheffield Scientific School of Yale University, led to the discovery that New Haven already possessed an equipment suitable for the inquiry much more complete than the plan Professor Foster had outlined as being desirable.

At Yale were found not only a very well-adapted chemico-physiological laboratory with some of the most active and scientifically respected research talent of the world in charge, but the laboratory stood only three minutes away from one of the best furnished gymnasiums in the world, under a director who is an M. D. of twenty years' experience, as well as a famous athlete and author of an athletic manual. It so happened that this gymnasium was especially suited for assisting in a research into the very causes of human efficiency, or lack of it, which nutrition is supposed to affect.

Only forty minutes from New Haven by rail,--a distance not greater, as measured by time separation, than from one side of London to the other,--at Middletown, Conn., stood also the recently completed calorimeter of Professors Atwater and Benedict ready for making a calorimetric trial-balance measurement of metabolism attained and chemically estimated in the tests at New Haven.

After the Yale demonstration, of which Professor Chittenden's article, previously mentioned, treats, the author responded to an invitation from Professor Atwater and submitted himself to a 32-hour confinement in the calorimeter for confirmation of the results obtained at New Haven.

This experience in the calorimeter at Middletown was very significant and instructive. The author was the first test-subject used in the newly completed calorimeter. The oxygen-measuring attachment of Dr. Benedict that completed the apparatus and gave a complete trial balance of the metabolism of the subject under examination was as yet untried, but it proved its integrity within the fraction of one per cent and registered as accurately as necessary for all practical purposes. So much for the machine; but it measured a result which is of the greatest importance to the human race. The author had just demonstrated the possibility of running the human machine on half the heat, on one-third of the fuel, and with only one-tenth of the waste, as represented by the waste, or ashes of digestion. Not only was this done while in pursuit of the ordinary activity of present-day life, but under stress of 'Varsity-Crew exercise, as reported by Professor Chittenden and Dr. Anderson. Had this demonstration been made relative to steam engines or electrical motors, the information would have been revolutionary in establishing new values for things industrial and commercial.

Its significance relative to human profitable possibilities is even more important than if related to steam or electrical power. The possibility of economy in the human machine gives also a hope of immunity from the common diseases which now afflict mankind.

The trial of the calorimeter as a measuring machine and the trial balance of the economic metabolism which the author had attained by five years of careful attention to the natural requirements of nutrition were epoch-making events coincidently related, and for them the author here makes this distinguished claim--not on account of any accomplishment of himself, but as a promise of great possibilities for human betterment.

Here follows a reproduction of the plan just referred to, with _fac-simile_ of the signatures of the distinguished physiologists who approved the plan and consented to serve as "Assessors." To this list should have been added the name of Professor Ozawa, professor of physiology at the University of Tokio, Japan; but time and distance did not permit gaining the required understanding and assent. Professor Ozawa's connection with the inquiry would make it not only international but interhemispherical and interracial as well, and this possibility of scientific coördination and coöperation is typical of the harmonising wave that is fast enveloping the earth for the benefit of mankind.

I give a copy of the document entire, with estimates of cost, etc., just as it was originally drawn and intended only as a trial suggestion, to be modified by circumstances.—HORACE FLETCHER.]

PROPOSAL TO FOUND AN INTERNATIONAL LABORATORY OF RESEARCH FOR THE STUDY OF NUTRITION IN ALL ITS ASPECTS

Notwithstanding the enormous development which the study of Experimental Physiology has undergone during the last half-century, and the constant multiplication of physiological laboratories fitted in a manner which enables them to be used as places of research as well as of instruction in the methods of physiological inquiry, it has appeared to many physiologists that a great need remains to be supplied by the establishment of an International Laboratory of Research, devoted primarily, if not exclusively, to the investigation of problems connected with the Nutrition of the Animal, and particularly of Human Organisms,--studies particularly, and in the first instance, from the point of view of the relation of the food consumed by the animal body to its output of energy, either in the form of heat or mechanical work.

The reason for establishing such a laboratory, available for the use of investigations of all nations, is to be found in the fact that the researches which are now called for, in order to place upon a firm foundation our knowledge of food and its relations to the activity of the organism, necessitates an assemblage of apparatus and machinery so specialised and so costly that they are not to be found collected together even in the best equipped of the physiological laboratories of Europe or America, which all subserve in the first instance the purposes of systematic instruction. Undoubtedly, unquestionably, certain of the great and costly appliances of research are to be found in particular laboratories, as, for instance, in those of Berlin, Munich, Paris, and Turin, but there certainly exists no laboratory in which the investigator can find assembled under one roof all the specially fitted chemical, physical, and even bacteriological appliances which he may need to employ in the investigation of the Phenomena of Nutrition.

A more precise conception of the nature of the proposed laboratory may be formed if reference is made to certain groups of appliances which such a laboratory should possess and be able to place at the disposal of the scientific men coming to it for facilities which may be denied them at home. It should possess a complete set of respiration chambers of various types, and especially should be provided with the “Atwater Respiration Apparatus;” the most perfect appliances for the analyses of gases should be available; it should be provided with the most perfect calorimeters of various types, both for the investigation of the calorimetric value of the foods experimented on, and for the determination of the heat produced by man or by the lower animals,--the subjects of observation. The laboratory should possess, besides, the most perfect appliances for the measurement of work done by man and by animals (“ergostat,” “ergograph”), and a set of balances of the highest perfection capable of weighing with accuracy very heavy loads. These characteristic appliances of a laboratory specially designed for placing our knowledge of Animal Nutrition on a thoroughly sound basis must be superadded to the ordinary means for pursuing with success researches in Pure Organic, Physiological, and Physical Chemistry, as well as in Bacteriology.

OUTLINE OF THE PROPOSED SUBJECTS OF RESEARCH TO BE UNDERTAKEN IN THE PROPOSED INTERNATIONAL LABORATORY

1. To determine with greater precision than has yet been possible the efficiency of the animal organism considered as a machine in which potential energy of the organic constituents of food is converted into mechanical work. The knowledge that we already possess has shown that in the animal we have an engine infinitely more efficient as a utiliser of the potential energy supplied to it than any appliance yet constructed, or which we can, in the present state of physical science, construct. A still more precise study of the actual efficiency of the animal as a whole, as well as of certain of the vital organs which are mainly concerned in mechanical work, and a more thorough investigation of the processes whereby--for instance, in the muscles--the potential energy of stored-up chemical compounds is, as appears certain, directly converted into mechanical work, is not only desirable in the interest of the ultimate object of the work of the Laboratory, but possesses a high degree of theoretical interest, even from the point of view of Pure Physics. To sum up: One of the first objects of the investigations to be carried out in the projected Laboratory should be “the more precise determination of the minimum transformation of energy which corresponds to mean and accurately determined conditions of the animal body, and of that of man in particular.”

2. We are acquainted with the fact that the potential energy which is utilised by the animal is supplied to it with the least wear and tear to, or strain upon, its mechanism by non-nitrogenous organic constituents of food which must belong to the groups of starches and sugars or fats, but that the continued existence of the organism demands, as an essential condition, the introduction of a certain proportion of albuminous matter. In spite of numerous very fine investigations on this subject, the yet more precise determination of the minimum quantity of the albuminous constituents which are absolutely necessary or desirable, under the most varying conditions, is eminently desirable, especially in the light of recently recorded facts, amongst which are those to be referred to under 3 (following):—

3. Certain very noteworthy observations made by Messrs. Horace Fletcher and Ernest H. Van Someren have shown that an excessively prolonged mastication and insalivation of food leads to remarkable results in respect to the diminution of the total

quantity of food necessary to keep the body in a state of health, and to, as is alleged, a remarkable improvement in the digestive functions as well as of the general health of the individual. It appears highly important thoroughly to investigate the remarkable phenomena discovered by Messrs. Fletcher and Van Someren, and to determine how far they may lead to a modification of or improvement in the dietary of healthy individuals and of persons in a state of disease.

4. Indeed, it may truly be said that the average diet of man, that is to say, the absolute and relative amount of certain food-stuffs on which an average man should live, is at present, to a large extent, determined in an empirical manner. It is most necessary that this should be determined in an exact manner, since it is at least possible that a more complete knowledge may reveal that the good results thus obtained empirically are only reached by means of an excess of one element being counterbalanced by excess of another element, and thus open up a way to considerable economy. The changes needed for variations from the average, to meet certain conditions, are also at present, to a very large extent, determined empirically, and these also most certainly ought to be determined in an absolutely exact manner.

5. The researches of Pawlow on the conditions which influence the activity of the secreting glands of the organs of digestion, upon the relation of their activity to the nature of the food ingested, upon the influence exerted by the secretion of the glands situated in one part of the alimentary canal, upon the activity of glands situated lower down, indicate lines of research only recently opened out, but the importance of which in reference to the problems of nutrition is probably great.

6. Similarly, the facts which have in recent times been ascertained in reference to the remarkable influence exerted by the so-called “internal secretion” of certain ductless glands on the general metabolism, the part played by the pancreas in reference to the transformations of sugar in the body indicate yet other lines of research to be carried out in connection with the main inquiry.

In conclusion: The final problem of the work of the proposed Laboratory will be to ascertain the conditions which will “render it possible to obtain from the human machine, under varying conditions, the highest efficiency at the least cost.”

The value of results which may be thus obtained, considered from the point of view of social, political, and administrative economy, is hardly to be exaggerated.

SUGGESTIONS AS TO STAFF AND PERSONNEL OF THE PROPOSED INTERNATIONAL LABORATORY

For the coördination and general direction of the several investigations, the services of an eminent physiological chemist (preferably one having the principal European languages at his command) is essential.

Such a director would need at least two efficient permanent technical assistants, as for instance, one to deal with the problems of Organic Chemistry, and another competent to deal with the problems of Physical Chemistry. Other assistants might be necessary, but it would probably be desirable that the Institute should have the power of subsidising, for a longer or shorter period, men who would undertake special investigations in coördination with the general work, and who would thus be, as it were, temporary assistants. This would be quite apart from the general hospitality of the Laboratory offered by the Institute to other investigators.

ESTIMATES FOR THE PROPOSED LABORATORY

INITIAL OUTLAY

Director $5,000 $5,000 Permanent and Temporary Assistants 7,500 to 10,000 Other General Maintenance 5,000 to 7,500 ——————— ——————— — $17,500 $22,500

With regard to the second item, the permanent assistants would be required at the outset, but the temporary assistants would be taken on as opportunity offered. Less than even the lower estimate might suffice at first.

Regarding the third item, also, the maximum might not be required in the beginning.

SUGGESTIONS AS TO DESIRABILITY OF LOCATION

The place fitted for the establishment of an International Institute should be one which can be reached with comparative facility by investigators of the different nationalities. It must be one free from the objections due to national susceptibilities. It should also be, if possible, a place agreeable to live in; a place where work can be carried on through the year; and a place where expenses, both the personal expenses of the investigators, and the general expenses of the Institute, are not excessive. Venice has been

suggested as a place fulfilling the above requirements. It can be reached readily from all parts of Europe, and is as accessible to Americans as any other European city. Living is very cheap, and, indeed, all expenses are very moderate.

On sea level itself, Venice is within near distance of very high altitude, and hence offers facilities for the study of the effects of climatic influence on nutrition. It is also sufficiently near the Regina Margherita Laboratory, on Monte Rosa, to enable the observations made at the two places to be coördinated. Venice is, moreover, a cosmopolitan centre; and persons of many different nations and races might readily be obtained as subjects for observation and experiment.

On the other hand, it may be regarded as essential to the complete success of the proposed Institute that both the director and those engaged in investigation should have ample opportunities of ready and frequent intercourse with eminent men engaged in investigation in Physics, Chemistry, and the allied sciences. The help which is thus gained by intercourse with men at the very head of various scientific inquiry cannot be supplied in any other way. There is also an urgent reason for ready access to a most thoroughly equipped scientific library. It is also essential that the Institute should have facility of obtaining, or of getting constructed, with the least possible delay such apparatus as it might need. These essentials cannot be supplied otherwhere than in great centres of scientific activity. A small university cannot supply them. If they are insisted on, the Institute must be located in a place which has metropolitan distinction and holds not only a large but an active university. The choice of a situation, from this point of view, in Europe, is thus almost limited to such places as Paris, Berlin, Vienna, or London. Of these London probably best recommends itself for international purposes.

But, on the other hand, London is distinctly an expensive place to live in. Indeed, all expenses there are great, and the same may be said of any great metropolitan centre. Moreover, London cannot be reached from the countries of Europe without sea transit.

The choice between such a place as London and such a place as Venice must depend upon the relative weight attached, on the one hand, to the scientific advantages dwelt on above, and, on the other hand, to the advantages other than scientific.

SUGGESTIONS AS TO MANAGEMENT OF THE PROPOSED INTERNATIONAL INSTITUTE

It is proposed that: First, there should be a small body of trustees who should undertake the financial responsibility; and, Second, a board of scientific assessors, representing several nations, who, in conjunction with the director, should exercise general supervision of the work of the Institute. Such a board need meet only at rare intervals, much being done by way of correspondence. The expenses which the members incur in the exercise of their functions ought to be met out of the funds of the Institute.

The following have expressed willingness to act as scientific assessors:—

[Illustration: Signatures]

NATIONALITY AND SCIENTIFIC TITLES OF OUR BOARD OF SCIENTIFIC ASSESSORS

SIR MICHAEL FOSTER, M.D., K.C.B., F.R.S., M.P., etc. Late Professor of Physiology, University of Cambridge, England; Secretary of the Royal Society; Permanent Honorary President of the International Congress of Physiologists, etc.

DR. PROFESSOR ANGELO MOSSO. Professor of Physiology, University of Turin, Italy; Director of the Regina Margherita Biological Station on the summit of Monte Rosa, etc.

DR. PROFESSOR HUGO KRONECKER. Professor of Physiology, University of Berne, Berne, Switzerland, etc.

DR. PROFESSOR N. ZUNTZ. Professor of Physiology, Berlin, Germany, etc.

DR. PROFESSOR PAUL HEGER. Professor of Physiology, Brussels, Belgium; Director of the Solvay Sociological Institute, Brussels.

DR. PROFESSOR A. DASTRE. Professor of Physiology, Universitie de la Sorbonne, Paris, France, etc.

DR. PROFESSOR HENRY PICKERING BOWDITCH, Professor of Physiology, Harvard Medical School; Second President American Physiological Society; President of the Children’s Aid Society, Boston, Mass., etc.

PROFESSOR RUSSELL H. CHITTENDEN. Director Sheffield Scientific School of Yale University; Professor of Physiological Chemistry in Yale; Present President of the American Physiological Society, etc.

DR. PROFESSOR WILLIAM H. WELCH. Professor of Pathology in Johns Hopkins University, Baltimore, Maryland; President of the Rockefeller Institute of Preventive Medicine, etc.

DR. PROFESSOR J. P. PAWLOW. Director of the Department of Experimental Physiology in the Russian Imperial Military School of Medicine, etc.

PERSISTENT SCIENTIFIC DOUBTS

[Notwithstanding the report of the Cambridge examination of the claims for an economic nutrition advanced by the authors, American physiologists were still doubtful if a nitrogenous economy like that reported could be maintained, and the writer was invited to submit to further tests at the Physiological Laboratory of Yale University, under direction of Professor Russell H. Chittenden, Director of the Sheffield Scientific School, and President of the American Physiological Society, and Dr. Lafayette B. Mendel.

The following article, first published in the _Popular Science Monthly_, June, 1903, is a report of that test, and indicates a desire to carry the investigation further to include a variety of test-subjects.

In response to Professor Chittenden's request, the Trustees of the Bache Fund of the National Academy of Sciences appropriated $1000 towards a more extended inquiry; and other means having been assured, a project of experiments was taken under consideration.

One of the difficulties encountered was the control of test-subjects for a sufficiently long time to make conclusive estimates relative to the minimum needs of nitrogenous food in relation to the common occupations of life. Few if any volunteers, with the leisure and interest fortunately possessed by the writer, were available outside the laboratory force itself, and there were serious objections to using for test-subjects the same persons who did the chemical analyses and estimated the results.

In this dilemma the good fortune of a meeting with Surgeon-General O'Reilly of the United States Army and with General Leonard Wood--the former on his way to Madrid to attend a medical congress, and the latter _en route_ to the Philippines to take command there--happened to the writer on the S. S. _Commonwealth_, on a voyage to Italy in April, 1903.

Both these officers are medical men and research enthusiasts. They had fought yellow fever together, in coöperation with martyr Dr. Major Walter Reed, in Cuba, and the fame of their success was being talked of as one of the great triumphs of pathologic, or hygienic, science at the time of the meeting.

There was ample time on the steamer to discuss a subject of such mutual and general interest, and both officers had had, in service, experiences that led them to believe that the results obtained by the writer and his colleagues were the common possibilities of all persons under right conditions of alimentation.

General O'Reilly was of the opinion that the corps he commanded could furnish intelligent and earnest test-subjects for nutrition investigation, as it did in the yellow fever case. In the yellow fever investigation privates and officers alike had volunteered to act as test-subjects, even though their lives were at stake and many had already been sacrificed. It is to their great honour, also, that they refused to receive the bounty that was offered for test-subjects, preferring to serve science and humanity freely as volunteers rather than sell themselves as experimental risks. From such material General O'Reilly was sure that capable assistants could be secured to test the not at all dangerous or disagreeable economies of nutrition that the projected inquiry wished to solve.

Armed with letters of recommendation to the President and to the Secretary of War from General Wood, and an invitation from Surgeon-General O'Reilly to call on him if coöperation on his part were desired, the writer returned to the United States and consulted with Professors Chittenden and Bowditch relative to the desirability of army coöperation. It was believed to be just the thing wanted to facilitate the inquiry, and the writer proceeded to Washington to effect the combination.

General O'Reilly had already had the matter under consideration and was quite ready to draw up a project for presentation to the Secretary of War when Mr. Root should return to Washington from his summer vacation.

Twenty privates and three non-commissioned officers of the Hospital Corps of the United States Army under command of Dr. Lieutenant Wallace DeWitt are now quartered at New Haven in coöperation with the staff of the Sheffield Scientific School. It is the intention to learn, if possible, how little nitrogen is necessary to secure the best human efficiency; and also, if possible, to ascertain

some measure of the evil effects of an excess of nitrogenous food as well as excess of food in general upon human efficiency.

The writer is grateful for the good fortune of being able to be of service in a development of interest in a subject which is of vital importance to the human race. He has enjoyed the benefits of an economic nutrition and knows its value.

The practical proof of a subject of personal application must come from such personal application. Each person must be his own doctor and his own scientist in the matter of his alimentation or he runs the risk of running amuck in his health economy. There is not so much to learn, neither is there very much to do to insure right alimentation, perfect digestion, and continuous good health; but the little required of us must be attended to with no lapses of attention.—HORACE FLETCHER.]

PHYSIOLOGICAL ECONOMY IN NUTRITION

BY RUSSELL H. CHITTENDEN

Director of the Sheffield Scientific School of Yale University

Among the many problems awaiting solution, none is of greater importance for the welfare of the individual and of the race than that which relates to the proper nutrition of the body. Man eats to live and to gain strength for his daily work, and without sufficient nutriment the machinery of the body cannot be run smoothly or with proper efficiency. The taking of an excess of food, on the other hand, is just as harmful as insufficient nourishment, involving, as it does, not only wasteful expenditure but, what is even of greater moment, an expenditure of energy on the part of the body, which may in the long run prove disastrous. While it is the function of food to supply the material from which the body can derive the necessary energy for its varied activities, any excess of food over and above what is needed to make good the loss incidental to life and daily activity is just so much of an incubus, which is bound to detract from the smooth running of the machinery and to diminish the fitness of the body for performing its normal functions.

A proper physiological condition begets a moral, mental, and physical fitness which cannot be attained in any other way. Further, it must be remembered that lack of a proper physiological condition of the body is more broadly responsible for moral, social, mental, and physical ills than any other factor that can be named. Poverty and vice on ultimate analysis may often be traced to a perversion of nutrition. A healthy state of the body is a necessary concomitant of mental and moral vigour, as well as of physical strength. Abnormal methods of living are often the accompaniment or forerunner of vicious tastes that might never have been developed under more strictly physiological conditions. Health, strength (mental and physical), and moral tone alike depend upon the proper fulfilment of the laws of nature, and it is the manifest duty of a people hoping for the fullest development of physical, mental, and moral strength to ascertain the character of these laws with a view to their proper observance. Poverty, crime, physical ills, and a blunted or perverted moral sense are the penalties we may be called upon to pay for the disobedience to Nature’s laws; penalties which not only _we_ may have to pay, but which may be passed down to succeeding generations, thereby influencing the lives of those yet unborn.

There is to-day great need for a thorough physiological study of those laws of nutrition which constitute the foundation of good living. It is a subject full of interest and promise for the sociologist and economist, as well as for the physiologist. We need a far more complete knowledge than we possess at present of the laws governing nutrition; we need fuller knowledge of the methods by which the most complete, satisfactory, and economical utilisation of the diet can be obtained; we need to know more concerning the minimum diet and the minimum amount of proteid or albuminous foods on which health, mental and physical vigour can be permanently maintained; we need to know more fully concerning the influence of various forms of food on growth and recuperative power; we need more complete knowledge regarding the rôle of various dietetic and digestive habits, fixed or acquired; the effects of thorough mastication, insalivation, and the influence of two versus three meals a day upon the utilisation of food and hence upon the bodily health. Further, we need more concise information as to the effect of the mental state upon digestion and nutrition. These and many other problems of a like nature confront us when we attempt to trace the influence of a proper nutrition upon the condition of the body. These problems, however, all admit of solution, and in their solution undoubtedly lies the remedy for many of the personal ills of mankind.

The foregoing thoughts have been suggested by observations recently made in the writer’s laboratory on the amount and character of the food actually required by a healthy man in the maintenance of bodily equilibrium in periods of rest and physical work. Our ideas at present are based primarily upon observations as to what civilised peoples are accustomed to do, and not upon what they need to do in order to meet the demands made upon the body. Sir William Roberts has well said that the palate is the dietetic conscience, but he adds that there are many misfit palates, and we may well query whether our dietetic consciences have not

become generally perverted through a false mode of living. The well-nigh universal habit of catering to our appetite on all occasions, of bowing to the fancied dictates of our palates even to the extent of satiety, and without regard to the physiological needs of the body, may quite naturally have resulted in a false standard of living, in which we have departed widely from the proper laws of nutrition. Statistical studies carried out on large groups of individuals by various physiologists have led to the general acceptance of dietary standards, such as those proposed by Voit, of Munich, and Atwater in this country. Thus the Voit diet for a man doing moderate work is 118 grams of proteid or albuminous food, 56 grams of fat, and 500 grams of carbohydrates, such as sugar and starch, with a total fuel value of 3,055 large calories or heat units per day. With hard work, Voit increases the daily requirement to 145 grams of proteid, 160 grams of fat, and 450 grams of carbohydrates, with a total fuel value of 3,370 large calories. Atwater, on the other hand, from his large number of observations, is inclined to place the daily proteid requirement at 125 grams, with sufficient fat and carbohydrate to equal a total fuel value of 3,500 large calories for a man doing a moderate amount of work; while for a man at hard work the daily diet is increased to 150 grams of proteid, and with fats and carbohydrates to yield a total fuel value of 4,500 large calories. These standards are very generally accepted as being the requirement for the average individual under the given conditions of work, and it may be that these figures actually represent the daily needs of the body. Suppose, on the other hand, that we have in these figures false standards, or, in other words, that the quantities of food-stuffs called for are altogether larger than the actual demands of the body require. In this case there is a positive waste of valuable food material which we may calculate in dollars and cents; a loss of income incurred daily which might be expended more profitably in other directions. To the wage-earner with a large family, who must of necessity husband his resources, there is in our hypothesis a suggestion of material gain not to be disregarded. The money thus saved might be expended for the education of the children, for the purchase of household treasures tending to elevate the moral and mental state of the occupants, or in many other ways that the imagination can easily supply. This kind of saving, however, is purely a question of economy, and in some strata of society would be objected to as indicative of a condition of sordidness. It has come to be a part of our personal pride to have a well-supplied table, and to eat largely and freely of the good things provided. The poorer man takes pride in furnishing his family with a diet rich in expensive articles of food, and imagines that by so doing he is inciting them to heartier consumption and to increased health and strength. He would be ashamed to save in this way, under the honest belief that by so doing he might endanger the health of his dear ones. But let us suppose that this hypothetical waste of food is not merely uneconomical, that it is undesirable for other and weightier reasons. Indeed, let us suppose that this unnecessary consumption of food is distinctly harmful to the body, that it is physiologically uneconomical, and that in our efforts to maintain a high degree of efficiency we are in reality putting upon the machinery of the body a heavy and entirely uncalled-for strain, which is bound to prove more or less detrimental. If there is truth in this assumption, our hypothesis takes on a deeper significance, and we may well inquire whether there are any reasonable grounds for doubting the accuracy of our present dietary standards.

In this connection it is to be remembered that the food of mankind may be classified under three heads, viz., _proteid or albuminous_, such as meat, eggs, casein of milk, gluten of bread, and various vegetable proteids; _carbohydrates_, as sugar and the starches of our cereals, and _fats_, including those of both animal and vegetable origin. The proteids are characterised by containing nitrogen (about 16 per cent), while the fats and carbohydrates contain only carbon, hydrogen, and oxygen. The two latter classes of food-stuffs are burned up in the body, when completely utilised, to carbonic acid (a gas) and water, while the proteid foods, beside yielding carbonic acid and water, give off practically all of their nitrogen in the form of crystalline nitrogenous products in the excreta of the body. Proteid foods have a particular function to perform, viz., to supply the waste of proteid matter from the active tissues of the body, and this function can be performed only by the proteid foods; hence the latter are essential food-stuffs without which the body cannot long survive. Fats and carbohydrates, on the other hand, are mainly of value for the energy they yield on oxidation, and in this connection it is to be remembered that the fuel value of fats per gram is much larger than that of carbohydrates, viz., 9.3: 4.1, or more than twice as great. Further, it is to be noted that the various food-stuffs cannot be utilised directly by the body, but they must first be digested, then absorbed and assimilated, after which they gradually, in their changed form, undergo decomposition with liberation of their contained energy, which may manifest itself in the form of heat or of mechanical work. The thoroughness with which foods are digested and utilised in the body must therefore count for a great deal in determining their dietetic or nutritive value. Moreover, it is easy to see how an excess of proteid food will give rise to a large proportion of nitrogenous waste matter, which, floating through the system prior to excretion, may, by acting on the nervous system and other parts of the body, produce disagreeable results. A mere excess of food, even of the non-nitrogenous variety, must entail a large amount of unnecessary work, thereby using up a proportional amount of energy for its own disposal, since once introduced into the body it must be digested and absorbed, otherwise it undergoes fermentation and putrefaction in the stomach and intestines, causing countless troubles. When absorbed in quantities beyond the real needs of the body, it may be temporarily deposited as fat; but why load up the system with unnecessary material, thereby interfering with the free running of the machinery?

In other words, it is very evident that the taking in of food in quantities beyond the physiological requirements is undesirable, and may prove exceedingly injurious. It is truly uneconomical, and defeats the very ends we aim to attain. Instead of adding to the bodily vigour and increasing the fitness of the organism to do its daily work, we are really hampering the delicate mechanism, upon the smooth running of which so much depends.

Why, now, should we assume that a daily diet of over 100 grams of proteid, with fats and carbohydrates sufficient to make up a fuel value of over 3,000 large calories, is a necessary requisite for bodily vigour and physical and mental fitness? Mainly because of the supposition that true dietary standards may be learned by observing the relative amounts of nutrients actually consumed by a large number of individuals so situated that the choice of food is unrestricted. But this does not constitute very sound evidence. It certainly is not above criticism. We may well ask ourselves whether man has yet learned wisdom with regard to himself, and whether his instincts or appetites are to be entirely trusted as safe guides to follow in the matter of his own nutrition. The experiments of Kumagawa, Sivén, and other physiologists, have certainly shown that men may live and thrive, for a time at least, on amounts of proteid per day equal to only one-half and one-quarter the amount called for in the Voit standard. Sivén's experiments, in particular, certainly indicate that the human organism can maintain itself in nitrogenous equilibrium with far smaller amounts of proteid in the diet than is ordinarily taught, and, further, that this condition can be attained without unduly increasing the total calories of the food intake. Such investigations, however, have always called forth critical comment from writers on nutrition, indicating a reluctance to depart from the current doctrines of the Voit or Munich school; and, indeed, it may justly be claimed that the ordinary nutrition experiments, extending over short periods of time, are not entirely adequate to prove the effect of a given set of conditions when the latter are continued for months or years. Thus, Schäfer writes: "It may be doubted whether a diet which includes considerably less proteid than 100 grams for the twenty-four hours could maintain a man of average size and weight for an indefinite time. It has frequently been asserted that many Asiatics consume a very much smaller proportion of proteid than is the case with Europeans. The inhabitants of India, Japan, and China chiefly consume rice as the normal constituent of their diet, which contains relatively little proteid; and this has been advanced as an argument in favour of the view that the minimal amount of proteid is much less than that ordinarily given as essential to the maintenance of nutritive equilibrium. It must, however, be stated that we have no definite statistics to show that, in proportion to their body-weight, Asiatics doing the same amount of work as Europeans require a less amount of proteids; indeed such evidence as is forthcoming is rather in favor of the opposite view." This statement is typical of the attitude of physiologists in general on this important subject. Why not candidly admit that the matter is in doubt, and, with a due recognition of the importance of the subject, attempt to ascertain the real truth of the matter?

The writer has had in his laboratory for several months past a gentleman (H. F.) who has for some five years, in pursuit of a study of the subject of human nutrition, practised a certain degree of abstinence in the taking of food and attained important economy with, as he believes, great gain in bodily and mental vigour, and with marked improvement in his general health. Under his new method of living he finds himself possessed of a peculiar fitness for work of all kinds, and with freedom from the ordinary fatigue incidental to extra physical exertion. In using the word abstinence possibly a wrong impression is given, for the habits of life now followed have resulted in the disappearance of the ordinary craving for food. In other words, the gentleman in question fully satisfies his appetite, but no longer desires the amount of food consumed by most individuals.

For a period of thirteen days, in January, he was under observation in the writer's laboratory, his excretions being analysed daily with a view to ascertaining the exact amount of proteid consumed. The results showed that the average daily amount of proteid metabolised was 41.25 grams, the body-weight (165 pounds) remaining practically constant. Especially noteworthy, also, was the very complete utilisation of the proteid food during this period of observation. It will be observed here that the daily amount of proteid food taken was less than one half that of the minimum Voit standard, and it should also be mentioned that this apparent deficiency in proteid food was not made good by any large consumption of fats or carbohydrates. Further, there was no restriction in diet. On the contrary, there was perfect freedom of choice, and the instructions given were to follow his usual dietetic habits. Analysis of the excretions showed an output of nitrogen equal to the breaking down of 41.25 grams of proteid per day as an average, the extremes being 33.06 grams and 47.05 grams of proteid.

In February a more thorough series of observations was made, involving a careful analysis of the daily diet, together with analysis of the excreta, so that not alone the proteid consumption might be ascertained, but likewise the total intake of fats and carbohydrates. The diet consumed was quite simple, and consisted merely of a prepared cereal food, milk, and maple sugar. This diet was taken twice a day for seven days, and was selected by the subject as giving sufficient variety for his needs and quite in accord with his taste. No attempt was made to conform to any given standard of quantity, but the subject took each day such amounts of the above foods as his appetite craved. Each portion taken, however, was carefully weighed in the laboratory, the

chemical composition of the food determined, and the fuel value calculated by the usual methods.

The following table gives the daily intake of proteids, fats, and carbohydrates for six days, together with the calculated fuel value, and also the nitrogen intake, together with the nitrogen output through the excreta. Many other data were obtained showing diminished excretion of uric acid, ethereal sulphates, phosphoric acid, etc., but they need not be discussed here.

■■■

My conclusion, given in condensed form, is this: Mr. Fletcher performs this work with greater ease and with fewer noticeable bad results than any man of his age and condition I have ever worked with.

To appreciate the full significance of this report, it must be remembered that Mr. Fletcher had for several months past taken practically no exercise other than that involved in daily walks about town.

In view of the strenuous work imposed during the above four days, it is quite evident that the body had need of a certain amount of nutritive material. Yet the work was done without apparently drawing upon any reserve the body may have possessed. The diet, small though it was, and with only half the accepted requirement in fuel value, still sufficed to furnish the requisite energy. The work was accomplished with perfect ease, without strain, without the usual resultant lameness, without taxing the heart or lungs, and without loss of body-weight. In other words, in Mr. Fletcher's case at least, the body machinery was kept in perfect fitness without the consumption of any such quantities of fuel as has generally been considered necessary.

Just here it may be instructive to observe that the food consumed by Mr. Fletcher during this seven days' period--and which has been shown to be entirely adequate for his bodily needs during strenuous activity--cost eleven cents daily, thus making the total cost for the seven days seventy-seven cents! If we contrast this figure with the amounts generally paid for average nourishment for a like period of time, there is certainly food for serious thought. Mr. Fletcher avers that he has followed his present plan of living for nearly five years; he usually takes two meals a day; has been led to a strong liking for sugar and carbohydrates in general and away from a meat diet; is always in perfect health, and is constantly in a condition of fitness for work. He practises thorough mastication, with more complete insalivation of the food (liquid as well as solid) than is usual, thereby insuring more complete and ready digestion and a more thorough utilisation of the nutritive portions of the food.

In view of these results, are we not justified in asking ourselves whether we have yet attained a clear comprehension of the real requirements of the body in the matter of daily nutriment? Whether we fully comprehend the best and most economical method of maintaining the body in a state of physiological fitness? The case of Mr. Fletcher, just described; the results noted in connection with certain Asiatic peoples; the fruitarians and _nut_arians in our own country recently studied by Professor Jaffa, of the University of California; all suggest the possibility of much greater physiological economy than we as a race are wont to practise. If these are merely exceptional cases, we need to know it; but if, on the other hand, it is possible for mankind in general to maintain proper nutritive conditions on dietary standards far below those now accepted as necessary, it is time for us to ascertain that fact. For, if our standards are now unnecessarily high, then surely we are not only practising an uneconomical method of sustaining life, but we are subjecting ourselves to conditions the reverse of physiological, and which must of necessity be inimical to our well-being. The possibility of more scientific knowledge of the natural requirements of a healthy nutrition is made brighter by the fact that the economic results noted in connection with our metabolism examination of Mr. Fletcher is confirmatory of similar results obtained under the direction and scrutiny of Sir Michael Foster at the University of Cambridge, England, during the autumn and winter of last year; and by Dr. Ernest Van Someren, Mr. Fletcher's _collaborateur_, in Venice, on subjects of various ages and of both sexes, some account of which has already been presented to the British Medical Association and to the International Congress of Physiologists at its last meeting at Turin, Italy. At the same time emphasis must be laid upon the fact that no definite and positive conclusions can be arrived at, except as the result of careful experiments and observations on many individuals covering long periods of time. This, however, the writer hopes to do in the very near future, with the coöperation of a corps of interested observers.

The problem is far-reaching. It involves not alone the individual, but society as a whole, for beyond the individual lies the broader field of the community, and what proves helpful for the one will eventually react for the betterment of society, and for the improvement of mankind in general.

INTRODUCTION TO DR. HARRY CAMPBELL'S CONTRIBUTION ON THE IMPORTANCE OF MASTICATION

[Since the publication of Van Someren's paper, "Was Luigi Cornaro Right?", read before the British Medical Association, and reprinted elsewhere in this volume, much more attention has been given to the study of mastication than had been previously reported. Mr. Gladstone's advice to his children, which was commonly current and was repeated whenever mastication was mentioned, was usually accompanied and met by an amused smile that showed that the full importance of better mouth-treatment of food was not appreciated. _Glutton or Epicure_, a little book by the present writer, published in 1898, insisted on thorough use of

the functions of the mouth in alimentation but did not go into the anatomical, physiological and dental details.

Dr. Harry Campbell of Northwest London Hospital has performed this latter service to science and humanity, with splendid carefulness, and must have devoted much time and study to the collection of evidence and suggestion which is given here following in full, reprinted from the _London Lancet_.

The authors acknowledge with much gratitude, the courteous permission of both Dr. Campbell and of the editor of the _Lancet_, to reprint all four articles which composed the series.

In our own study of the subject of mouth-treatment of food we have been led to give more credit to the chemical feature of preparation than Dr. Campbell yet attributes to the chemical side of the problem. Comminution of hard food is of first importance, undoubtedly, but insalivation and neutralisation or alkalinisation are, seemingly, much more easily and quickly accomplished in the mouth than farther on in the alimentary canal. The intestines _can_ do all in the way of digestion, even if the mouth and stomach are passed and their assistance in the digestive process is entirely neglected, but it is done at tremendous disadvantage in the supplementary digestive tract of the intestines. We have proven the economy of letting the mouth do _all it can_, by the insalivation (sipping and tasting) of liquids that have taste up to the point of compulsory swallowing (a sucking-up by the Swallowing Impulse which naturally occurs in the course of treatment in the mouth if not fought against too strongly). If Dr. Campbell will extend his observations to liquids, say milk, and for a sufficiently long time to measure results by continued economy of assimilation and saving of solid excreta, he will find that it pays to let the mouth do all it can do, and that while it _cannot do too much_ it _may do too little_. The natural instincts of the mouth, or those that attach to the mouth, become much more discriminating also if exercised on liquids as well as on solids. This they do not learn to do so well if sapid liquids are habitually rushed past their field of discrimination.

Taste enjoyed in the mouth is good, and a good part of the pleasure of living comes from taste gratification, but taste that returns from the stomach and is belched by eructation or is lingeringly reminiscent in the mouth or nose is indicative of indigestion.

Hence it is better to dissipate taste in the mouth, which is the sole region of taste. Spirits tasted into absorption in this way leave no odour upon the breath, and asparagus munched and tasted to the limit in the mouth, carries no odour to the urine. Even the stale and disagreeable odour of onion or garlic can be neutralised by saliva and killed in the mouth.

It is extremely difficult to get observers to practise tasting taste out of liquids as the wine tasters do, and as the tea tasters _have to do or die_; or, at least, become useless in their profession. Once the efficacy of the liquid-tasting precaution in digestion is understood, however, to swallow anything but pure water without tasting it into absorption produces a shock. This care becomes instinctive quite easily and regulates itself automatically. It is also a distinct gain to the gustatory possibilities, which are very limited at best.

When the body will tolerate spirits tasted into it--not poured into it--at all, which is not often when the nutrition is normal (only in damp or cold weather, as a general thing, and then in the case of the writer only at rare intervals, say two or three times a year), the spirit will mix quickly with the saliva and become neutralised sufficiently to excite the Swallowing Impulse. Continue sipping the spirit for a time and you will note that there comes a point where the saliva and the spirit do not mix, do not neutralise; the mouth becomes unduly full of liquid without any relaxation or invitation of the Swallowing Impulse; and the really instinctive inclination will be to _spit it out_. It is a clear indication that the body-_toleration_ has been fully taxed; there is no longer any bodily need for alcohol--in fact, there is no longer natural toleration--and the secretion sent down into the mouth is evidently mucous for a washing-out process, and is not alkaline saliva for assisting in a utilisation function.

It is quite uncanny to observe the nicety of mouth-discrimination and the consistency of it as related to similar substances under similar conditions, if one learn to read it with precision and intelligence.

With increased ease of digestion, which comes with more thorough attention to solid foods alone, the ordinary observer will think that he has accomplished the whole of the possible benefit. It is only when he gives sufficient time to liquids also, to get the added delight and relief that salivary respect of them brings, that the whole of the beneficence of mouth-service is realised. Follow this discrimination and care to a comparative measurement of the waste of digestion, the solid excreta, and note the increased proportionate gain in assimilation and the value of the economy will be appreciated. Try the different treatments on milk for a month; fifteen days with drinking and fifteen days insalivating (sipping and tasting) the milk to the limit, and keep account of quantity of intake required to satisfy appetite and maintain body-weight; and also note carefully the condition and quantity of the fæces. In

the one case you will find the waste to be _fæces_ indeed, and unmistakably worthy of the name; but in the case of sipping, tasting and insalivating the milk to the full satisfaction of the appetite, the _digestion-ash_ will assume quite a different amount and character and deserve a change of name. The proportions of the saving in our own experiments have approximated the difference between three and ten; that is, on a reduction of only one-third the quantity of food commonly ingested, but fully satisfying the sipping and tasting appetite, the quantity of solid excreta was only one-tenth of the other and of quite a different character, æsthetically considered.

While these suggestions do not discredit or affect the value of the purely mechanical side of the treatment as given by Dr. Campbell, and are not intended to be controversial, they are ventured as an amendment to be worked out in regard to liquids, which are, in fact, only an extreme of the pultaceous foods against which Dr. Campbell warns us as being subtly dangerous.

There is another point in our experiences and observations of the largest importance that may appropriately be introduced here: The treatment of all liquids in the manner suggested prevents intemperance of drinking as effectively as it does intemperance of eating.

When food is filtered into the body after having become liquified and made alkaline, or, at least neutral, by saliva, the appetite is given a chance to measure the needs of the body and to discriminate against excess. As soon as the point of complete saturation of any one deficiency is reached, the appetite is cut off, as short as possible to imagine, with no indication of stomach fullness. It will welcome a little of proteid in beans, cheese, eggs, or in some other of its richer forms, and then turn to sugar or fat in some of their numerous forms. Thirst for water will assert itself for a moment, sometimes asking but for a drop and again for a full glass, and afterwards, when near the point of complete saturation, appetite will hesitate for a moment, as if searching around for some rare substance, and may find its final satisfaction in a single spoonful of a sweet or a sip of something in sight.

The appetite satisfied by the infiltering process is a sweetly appeased appetite, calm, rested, contented, normal. There is no danger from the flooding of intemperance, for there is not even toleration of excess either of more food or of more drink, and this contented appetite will remain in the condition of contentment until another need has really been earned by evaporation or destructive katabolism.

In the teaching of this physiology and psychology of alimentation to the children of England, lies the only true solution of the drink question, which is now the curse of the nation.

Dr. Campbell has made such a splendid case for the mechanical side of mouth work, that it is the hope of the writer that he will give equally careful consideration to the chemical and psychological sides, and in a completeness of observation render inestimable service to his country, to science, and humanity. A decade of trial on the inmates of an infant orphan asylum will show the possibilities for the nation in a single generation, if broadly applied. It might lead to an effective intemperance, inhibition, or quarantine, and that is all any nation needs of advantage to make it independent of the world and truly great.—HORACE FLETCHER.]

OBSERVATIONS ON MASTICATION

BY HARRY CAMPBELL, M.D., F.R.C.P. (Lond.)

Physician to the Northwest London Hospital

[London _Lancet_, July 11, 18, 25, and August 8, 1903]

SECTION I. From _London Lancet_, July 11, 1903

THE EFFECTS OF MASTICATION

The primary object of mastication is to break up the food so as (1) to facilitate the swallowing of it, and (2), still more important, to insure its intimate admixture with the digestive juices, not only within the mouth, but throughout the entire digestive tract. Mastication has, however, other important and far-reaching effects. Thus it promotes the flow of saliva and, when properly performed, secures a due insalivation of the food; it increases the quantity of alkaline saliva passing into the stomach; it stimulates the heart and circulation; and it finally influences the nutrition of the jaws and their appendages by stimulating the local blood and lymph circulation. Now to consider these various objects and effects of mastication.

Mastication facilitates swallowing.--Many foods cannot be swallowed without first going through some preparation in the mouth. Soft, moist, pultaceous foods, such as milk pudding and porridge, can be and often, indeed, are swallowed with little or no preliminary chewing. On the other hand, it is a mechanical impossibility to swallow large lumps of tough food, or very dry food, even though, like flour, it be in a finely divided state. Dry food needs first to be well moistened; and it is not surprising that it promotes a more abundant flow of saliva than moist food, though the secretion thus excited may be poor in ferment. Hence it follows that if we desire to give foods which compel mastication, they should be tough or dry. On the whole, vegetable foods necessitate more thorough mastication than animal. The carnivora can scarcely be said to masticate at all the flesh which they consume; they simply tear off portions, and forthwith swallow them whole. Cooked flesh, however, does require mastication, owing to the coagulation of its proteids. The herbivora, on the other hand, unlike the carnivora, have to subject their food to considerable mastication before it can be swallowed; but they generally masticate it far more than is needful to render swallowing mechanically possible, as is exemplified in the act of rumination, the object here being to facilitate the admixture of the digestive juices with the food.

According to Van Someren, if the habit of masticating efficiently is once acquired, the food is not swallowed before it is converted into the liquid state, the swallowing of unmasticated lumps being effectually prevented by a pharyngeal reflex.

Mastication, by breaking the food up into small particles, enables it to be brought into intimate contact with the digestive juices.--Such comminution is especially needful in the case of raw vegetable foods of the tougher kind, in order to break up their cellulose framework, and to set free the contained starch, proteids, and fats. Foods of this kind, unless masticated, yield practically no nutriment to the organism. I cannot too strongly emphasise the fact that before man learned to break up the cellulose framework of his vegetable food by cooking he was compelled to subject it to laborious mastication. But, while thorough comminution is especially needed for vegetable food when raw, it is also needed for many cooked forms of it also,--as, for example, solid batter pudding and new underbaked bread, heavy lumps of which, passing into the stomach, may seriously hamper the work of that organ. Such substances are indigestible essentially by virtue of their impermeability to the digestive juices, and they gain in digestibility in proportion as they are comminuted. The indigestibility of new bread would appear to be wholly due, not to any peculiarity of chemical composition, but to its tendency to elude the teeth and form a sodden mass impermeable to the digestive juices, while the more powdery stale bread is more easily broken up both in the mouth and within the stomach. Cabbage, again, owes its indigestibility to the fact that it is allowed to pass into the stomach in large masses, while the well-known digestibility of cauliflower and minced spinach is due to the fineness of their division; were cabbage as finely minced as spinach usually is it would be equally digestible.

Turning now to animal food it has to be remarked that while in the raw state it may be readily digestible with little or no previous mastication, since massive pieces of it are readily attacked by the digestive juices, the like is much less true of animal food the proteids of which have been coagulated and rendered less permeable by cooking. Large lumps of hard-boiled egg or overdone meat, for instance, may obstinately resist gastric digestion; indeed, as with vegetable so with animal foods, their relative digestibility depends more upon physical consistence than chemical composition; beef is generally more indigestible than mutton and pork or veal than either, not so much by virtue of chemical composition as of physical consistence; the indigestibility of cheese illustrates the same truth; the individual nutritive ingredients of this substance--the proteids and fats--are not in themselves indigestible; casein in the form of protein or plasmon is known to be easy of digestion, and butter is one of the most digestible of fats; but in cheese the two are welded together into a comparatively impermeable mass, which is apt to escape comminution by the teeth and to pass down into the stomach in the form of solid lumps. A plain, wholesome cheese well masticated or intimately mixed with other foods, as in macaroni cheese, is quite easily digested by the majority.

I do not, of course, deny the influence of the chemical factor. Undoubtedly food may disturb digestion by virtue of its chemical composition, apart altogether from its physical characters; thus, while cooked goose-fat sets up violent irritation in some, others cannot tolerate eggs in any shape or form, and innumerable idiosyncrasies in respect of special articles of diet are met with which are essentially referable to chemical composition; but making due allowance for this chemical influence there can, I think, be little doubt that the digestibility of the more common articles of diet, both animal and vegetable, depends in the main upon their physical constitution, _all of them tending to be equally digestible when reduced to the same degree of comminution_. This, if true, is, I need scarcely say, a fact of the greatest practical importance, for it amounts to this: that we may often allow to those with very weak digestions foods which are generally considered indigestible, provided that they be thoroughly comminuted, whether by mastication or artificial means.

Mastication promotes the flow of saliva and the insalivation of the food.--The more efficiently food is masticated the greater is the salivary flow, and the more intimately is it mixed with the saliva, or, as we say, insalivated. The saliva has apparently no effect on

fats; whether it acts on proteids seems more doubtful, though by some authorities the penetration of these by the alkali of this fluid is said to aid in their subsequent digestion; on starch, however, the saliva acts very potently, and hence mastication plays a special part in promoting the digestion of starchy foods. Indeed, if only mastication be persisted in long enough, starch may be wholly converted into maltose within the mouth, and it need scarcely be said that it is better for the individual himself to manufacture his maltose in this way than that he should take it ready made for him in the form of one of the many “malt extracts” on the market. Patients are often forbidden starchy food, while they are allowed the maltose which they can quite well manufacture in their own mouths. Provided they be sufficiently insalivated, there are few starchy foods which are indigestible, not even excepting the proverbially indigestible new potato. These remarks are especially applicable to children, as will be more particularly insisted on later.

Mastication increases the amount of alkaline saliva passing into the stomach, and this not only prolongs the period of starch digestion within this organ but, by its influence upon the reaction of the gastric contents, influences all the digestive processes taking place there. I shall have occasion to point out later that a deficient supply of alkaline saliva in the stomach predisposes to certain forms of indigestion.

Mastication acts reflexly upon the stomach.--It is now known that the act of mastication influences the stomach reflexly, promoting the flow of gastric juice and thus preparing the stomach for the entrance of food into it. If the œsophagus of a dog is cut so as to allow the swallowed food to escape instead of passing into the stomach, it is found that the mastication of food causes a considerable flow of gastric juice. Food introduced into the stomach unaccompanied by mastication is less effective in promoting the gastric flow. It is probable that the influence of mastication on the flow of gastric juice is largely produced through the medium of psychic influences, for the more efficient the mastication the more is the sense of taste affected.

Mastication stimulates the heart and so promotes the general circulation.--This stimulating action may be partly due to its local action on the flow of blood and lymph in the jaws and accessory parts, and partly to a reflex influence, but whatever the explanation there can be no doubt of the fact. Hence the mere chewing of a non-nutritive substance, such as gum arabic, is stimulating, and, doubtless, the stimulating effects induced by the chewing of such articles as tobacco and betel are largely to be explained in this way.

THE INFLUENCE OF MASTICATION ON THE JAWS AND ADJACENT STRUCTURES

This subject is of such importance that it needs to be dealt with in some detail. By “adjacent structures” I mean the masticatory muscles, tongue, teeth, salivary glands, the nasal passages and sinuses pertaining thereto, the naso-pharynx, soft palate, and tonsils.

The muscles of mastication.--Let me at the outset draw attention to certain anatomical points, in connection with the muscles of mastication. These are (_a_) their massiveness; (_b_) the very close relation of the pterygoids to the naso-pharynx; and (_c_) the outward direction of the pterygoids.

(_a_) It is not until one studies the muscles of mastication closely that one comes to realise their massiveness. Their large size, in relation to the bony structures in connection with them, is well shown in a vertical transverse section of the head carried through the ascending ramus of the mandible[7] (see Fig. 1). It is evident that the functional activity of so large a mass of muscle tissue cannot but exercise considerable influence on the nutrition of the neighbouring parts.

[Illustration:

FIGURE 1.--Vertical transverse (slightly oblique) section through the head on a level with the epiglottis. The massiveness of the system of masticatory muscles is apparent.]

(_b_) The pterygoid muscles, springing as they do from the internal pterygoid plates, must necessarily be in close relation with the naso-pharynx, especially the internal pair, which take their origin from the internal aspect of the internal plates. I would further point out that the external pair, although they diverge from the naso-pharynx on their way to the mandibular condyles, yet remain on a level with that cavity. This close relation of the pterygoids to the naso-pharynx is, if I mistake not, of great importance in relation to the etiology of “adenoids.”

(_c_) Of the two pairs of pterygoids the external pair pass in the more outward direction, forming with the sagittal plane of the head an angle of 45° (see Figs. 1 and 2). In consequence of this direction they tend by their contraction to pull the pterygoid plates and

posterior parts of the maxilla away from the sagittal plane of the head, and thus to secure the normal width of the posterior nares. It is these muscles which bring about the lateral movements of the mandible, causing the lower teeth to move laterally and sagittally across the upper, the food being in this way far more effectually ground than by a mere vertical pressure of the teeth against one another. These lateral movements are, as we shall see, less pronounced among the moderns than among primitive peoples.

[Illustration: FIGURE 2.--Portion of horizontal section of head about an inch below the condyles of the lower jaw. The outward direction of the external pterygoids is well shown; also the close relation of the levatores and tensores palati with the internal pterygoids.]

The influence of the contraction of the masticatory muscles on the local circulation of blood and lymph.--When a muscle is at rest the blood flows sluggishly through it, while there is a complete, or all but complete, stagnation of the lymph current; if a lymphatic trunk of a limb at rest be cut no lymph escapes from it. Rhythmic muscle contractions, however, stimulate the flow both of blood and lymph (_a_), in the contracting muscles themselves and (_b_) in the neighbouring parts. (_a_) Not only are the muscle arteries dilated during rhythmic contractions, but the blood is vigorously squirted out of the muscle veins, so that much more blood flows through a muscle during its rhythmic contraction than during rest. The flow of lymph is even more markedly stimulated,--this fluid, which, while the muscle is at rest, is stagnant or all but so, being during contraction driven actively along the lymphatic trunks. (_b_) How greatly rhythmic muscle contractions influence the circulation of fluids in the neighbouring parts is shown by the flushing of the skin and the swelling of the soft parts generally of a limb which is being exercised. We thus see how profoundly the exercise of the masticatory muscles--and among these we must not forget to include the tongue--influences not only their own nutrition but that of the important structures adjacent to them--that is to say, of the jaw-bones, salivary glands, buccal mucous membrane, soft palate, faucial tonsils, pharynx, and naso-pharynx, as well as of the nasal cavities and their accessory sinuses. All these parts are during mastication copiously flushed with blood and lymph, from which it is evident that efficient mastication must stimulate their nutrition and favour their proper development. Hence, in one who has from childhood upwards been accustomed to masticate efficiently, we generally find these parts well developed, the jaws large and shapely, the teeth regular and straight, the tongue and salivary glands large, the nasal and naso-pharyngeal passages spacious, and the mucous membrane of the buccal and adjoining cavities healthy.

Influence of mastication on the jaw-bones.--It is well known that the size of a bone is largely determined by the degree to which the muscles attached to it are exercised. That the jaws do not grow to their normal size, if not adequately exercised during their period of growth, is strikingly shown by the overcrowding of the teeth, which takes place in those brought up on soft foods, and this even though there be no contraction of the jaws resulting from mouth-breathing. The dependence of the size of the jaws upon the degree to which they are exercised is also shown by the smallness of the modern jaw, as compared with that of primitive peoples, a difference which, as we shall see, is in part congenital and in part due to the comparative disuse of the former. Mastication influences not only the size but also the shape of the jaws (_a_), through its influence on the size of the tongue, which by pressing against the teeth tends, as Sim Wallace has shown, to expand the jaws; (_b_) by the pressure of opposing teeth against one another, which has a similar effect; and (_c_) by the outward pull of the pterygoids, which tends to widen the maxilla posteriorly and to broaden the posterior nares.

Influence of mastication on the teeth.--The teeth being developed within the jaw-bones and remaining, even after eruption, in close anatomical and physiological association with them, must necessarily share in their nutritive tendencies. If these bones are efficiently exercised during the formation of the teeth--and my remarks apply especially to the permanent set--the tooth-germs will be abundantly flushed with blood, while the ample growth of the jaws themselves will provide the germs with plenty of room in which to grow and to develop, and the more perfect their growth and development the more resistant should we expect them to be to the ravages of caries. Who can contemplate the jaw-bones of a six-years-old child, dissected so as to display all the imbedded teeth, without being assured of the effect of mastication upon dental development? Fifty-two teeth meet the view: the whole region from the orbital rims to the inferior border of the mandible is literally paved with them, and I can hardly doubt that they collectively weigh more than the bone in which they are imbedded. Surely no one can examine such a dissection without being convinced of the urgent necessity, if the teeth are to grow and to develop normally, of giving the child’s jaws from infancy onwards plenty of work to do.

The ample development of the jaws, which efficient mastication brings about, has a further beneficial effect as regards the teeth, in that it enables them to take up their proper places in the alveolar ridges, thus securing all the advantages of a good “bite.” These I now proceed to consider. The teeth during mastication, and especially when the bite is good and the food of a kind necessitating vigorous and sustained mastication, are made to move in their sockets both vertically and horizontally; the effect of this is to stimulate the circulation in the tooth-pulp, the alveolar periosteum (and hence also in the cementum and alveolar walls which are

supplied by it), and the circumjacent mucous membrane of the gum. All this makes for the health of the teeth; not only does it promote the nutrition of the tooth itself and of its bony socket, thus maintaining a firm dental setting, but it also tends to secure a healthy environment for the exposed part of the tooth--that part, namely, wherein caries begins--by maintaining a healthy state of the surrounding and, indeed, of the entire buccal mucous membrane, as well as of the various secretions which bathe the mouth. Wherefore it is not surprising to find that those who masticate efficiently suffer much less from dental caries and its complications (such as abscess at the root) and disease of the periodontal membrane (_e.g._, pyorrhœa alveolaris and loosening of the teeth) than those who are accustomed to bolt their food.

A few words as to the influence of mastication in wearing down the teeth. In those races which masticate vigorously the teeth in quite early adult life show signs of wearing away, while in later life it is quite common for the biting surfaces to be worn flat; sometimes the crown of the molars is worn away so that its surface shelves downwards and inwards and not infrequently it is concave, having a scooped-out appearance; often the dentine is exposed in this way; and yet among many hundreds of skulls examined I do not remember to have seen one single case where caries has started on the biting surface thus worn down.

I had always attributed this wearing down of the teeth to the friction of coarse food against them. Primitive races eat coarse vegetable food, which frequently contains grit, and this doubtless helps to grind the teeth down, but they may be markedly ground down even in those living on soft food, and in such cases the grinding away can obviously only be due to the friction of opposing teeth against one another. I, indeed, believe this to be the essential cause of the phenomenon, both in civilised races living on soft food and in primitive races whose coarse food necessitates prolonged and vigorous mastication and a corresponding amount of attrition between the biting surfaces of opposing teeth. In order that this attrition may occur two things are requisite: the upper and lower teeth must be well opposed--there must be a good bite--and mastication must be vigorous and of the right kind. Mere vertical pressure of the teeth against one another will not wear away the opposing surfaces; there must be friction of these surfaces against one another--a transverse and sagittal movement of the lower teeth against the upper by means of the pterygoids. Mainly to this do I attribute the marked wearing down of the teeth observed in primitive peoples, and I am gratified to know that so competent an authority on dental pathology as Sim Wallace is a convert to this view.

That all the teeth may be worn down just as we observe in primitive people, even in those who have lived all their lives on the ordinary fare of the moderns, is proved by a case I have under observation. It is that of a man in his fiftieth year, who was brought up in Belgium but who has resided in London for the last thirty years. When he came to my out-patient room I was not a little surprised to find that all his teeth were sound--a very unusual occurrence, I need hardly say, among the London poor at his age. In seeking for an explanation I elicited the fact that he was unable to swallow his food without chewing it very thoroughly, and on giving him a moderate-sized piece of bread, with the request that he should chew it in the ordinary way, I found that he subjected it to one hundred and twenty separate bites before swallowing it, and in the steady, deliberate way he went to work and in his extensive lateral movements of the mandible he reminded one for all the world of a cow chewing its cud. The temporals and masseters of this man are enormous, and the like is no doubt true of the pterygoids; he has well-developed nasal passages, has never suffered from nasal obstruction, while his buccal mucous membrane is unusually healthy for one of his years and circumstances. May we not attribute this healthy state of the mouth, teeth, and nose to the good effects upon them of efficient chewing? Here is a man who has lived for thirty years in London on the same kind of food as the average poor Londoner, but instead of finding his mouth full of carious, tartar-coated teeth, and spongy, receding, pus-exuding gums, we find thirty-two sound teeth firmly set in healthy gums and all but devoid of tartar.

A word as to the wearing down of the teeth in the anthropoid apes. In this respect the gorilla differs markedly from the orang and the chimpanzee. In all the skulls of these latter which I have examined the teeth show signs of wearing away, while I have found the teeth of the gorilla, with the exception of the tusk-like canines, but little worn. From this we should expect the latter animal to be mainly carnivorous, and the orang and chimpanzee to be largely herbivorous.

SECTION II. From _London Lancet_, July 18, 1903

CHANGES WHICH THE JAWS AND TEETH OF MAN HAVE UNDERGONE DURING MAN’S EVOLUTION FROM HIS ANTHROPOID ANCESTORS

During man’s progress upwards from the anthropoid his diet has undergone a progressive change, and a parallel adaptation has taken place in his jaws and teeth. Dietetically considered, we may divide his evolutionary career into the following epochs[8]: (1) the anthropoid stage; (2) the pre-cooking human stage; (3) the cooking pre-agricultural stage; (4) the early agricultural stage; and (5)

the late agricultural stage.

1. _The anthropoid stage._--The diet of man's anthropoid ancestors was probably much the same as is that of existing anthropoid apes; it consisted, namely, of raw vegetable and animal food, necessitating a vigorous use of the maxillary apparatus. This latter, we may assume, was of the type belonging to the anthropoids--_i. e._, the jaws were massive and markedly prognathic; the denture was the same as it is in existing man, but the teeth were larger, especially the upper canines, which served as weapons of offence and defence; the third molars (the wisdom teeth) were as large as the other molars and were provided with three fangs, and there was an ample portion of alveolar ridge behind them; there was no chin. No doubt the massiveness and the marked prognathism, which characterised the jaws at this stage, served other ends than that of mastication; it is obvious that projecting jaws and teeth are much more effectual for seizing and lacerating prey than are the orthognathic jaws of modern man.

2. _The pre-cooking human stage_ extends from the time man's ancestors first assumed the human form till they learned to apply fire in the preparation of their food. During all this period the jaws and teeth were probably used as much, or almost as much, for mastication as during the anthropoid stage; raw animal food had to be torn from the bones, the latter had to be crunched, while the bulk of the raw vegetable food needed then no less than it needs now prolonged and vigorous mastication in order to liberate the starch and other nutritive ingredients from their undigestible cellulose envelopes.[9] Nevertheless, the jaws and teeth underwent considerable change during this period, for not only were they with every advance in intelligence called less and less into requisition for purposes of offence and defence, but the jaws, at least, became materially modified in correlation with the expanding cranial cavity and in connection with the assumption of the erect posture. It is, I think, rather for these reasons than in consequence of alterations in the nature of the food that the masticatory apparatus now gradually lost its more bestial aspect and assumed an essentially human type, becoming towards the close of the period much the same as may be observed among the most primitive peoples now living.

3. _The pre-agricultural cooking period._--The characters of the maxillary apparatus belonging to this period are still available for study, the aboriginal Australians, the Bushmen, Negritos, and many Esquimaux not having yet emerged from it. So far as mastication is concerned, cooking influences vegetable far more than animal food, for it not only softens it but by rupturing the undigestible cellulose chambers and liberating their contents relieves mastication of one of its essential functions. Wherefore, with the advent of cooking, man's jaws and teeth began to get smaller, and they have continued to diminish in size up to the present time. No great diminution, however, took place at first, inasmuch as the diet still continued to be largely animal (and prior to the use of knives and forks such food had to be torn by the teeth), while the coarse vegetable food of this date, even when cooked, still needed laborious mastication. The chief differences between the maxillary apparatus of this early cooking age as compared with that of the present day are as follows: the jaws of the earlier period--_e. g._, in the aboriginal Australian--are more massive, and their sagittal diameter is greater, giving rise to decided prognathism, the teeth for the most part are larger and stronger, the third molars being nearly, if not quite, as big as the other molars, and provided with three fangs, while there is a considerable portion of alveolar ridge behind them. The third molars, however, show a decided tendency to be smaller than the rest, and the alveolar ridge behind them is less marked than in the previous period, features, I doubt not, attributable to the influence of cooking in diminishing mastication. Dental caries is rare and is chiefly met with in the third molars.

4. _The early agricultural age._--All the existing primitive races which have attained to the cultivation of the soil may be regarded as belonging to this period. Previously to it man was mainly carnivorous, owing to the comparatively limited quantity of vegetable food available, so long as the supply was left to nature alone; but when by cultivation this supply was increased and, at the same time, rendered more constant and certain, he gradually became less carnivorous and more vegetarian in his diet. The result of agriculture, however, is not only to increase the supply of vegetable food, but to diminish its fibrous, cellulosic ingredients, and thus to render it more easily masticated. Hence at this stage we find the maxillary apparatus becoming smaller than in the previous period, although the difference as shown--_e. g._, by the examinations of the skulls of the African negroes and the Melanesians--is less pronounced than we might perhaps have anticipated; prognathism is not so decided, the jaws are smaller, also the teeth, especially the third molars, which now for the first time show a tendency to be furnished with two instead of three fangs, while the alveolar ridge behind them is distinctly shorter than in the preceding period. Dental caries, hitherto rare, now becomes more frequent.

5. _The late agricultural period._--A mid-agricultural period might be described, but I shall take no account of it here, but pass on to a consideration of the late agricultural period--that, namely, in which we ourselves live. The chief characteristic of the food of this period is its softness. Cooked animal food requires, indeed, more mastication than raw, but the vegetable food of to-day, owing to the combined effects of improved agriculture, and skilful milling and cooking, is so soft as to excite comparatively little mastication.

The present may, in fact, be described as the _age of pap_. Hence the jaws and teeth are now called upon to perform far less work than in any earlier stage of our evolution, and there has taken place in consequence a great diminution in their size, more especially in the size of the jaws, so that there is now often no room for the teeth to take up their normal positions, and there is generally a complete absence of alveolar ridge behind the last molars. The latter are, moreover, apt to be very small or even absent, while dental caries is alarmingly frequent.

It will thus be seen that from the period of the anthropoids to the present time, a progressive change in the size and shape of the jaws and teeth has been taking place, a change which is to be explained by (1) the cessation of the need for using them for offensive and defensive purposes; (2) the growing capacity of the cranium and the assumption of the erect position; (3) the progressive alteration in man's diet; and probably also (4) considerations of beauty. The first three factors have operated through natural selection, the last through sexual selection, which has come into play, I would suggest, chiefly within recent times. Probably the most pronounced change which has taken place in the jaws during the agricultural periods has been the suppression of prognathism which, in the woman especially, is very unsightly, and tends to diminish the likelihood of marriage.

INSTANCES OF THE VIGOROUS USE TO WHICH THE JAWS AND TEETH ARE PUT AMONG EXISTING PRIMITIVE PEOPLES

A study of existing primitive peoples brings forcibly home to the mind how laboriously the jaws and teeth of our primitive ancestors were used. I have already shown how in pre-agricultural and early agricultural times the nature of the food compelled a sustained and vigorous exercise of these structures, and I wish here only to refer to a few specific and peculiar instances of laborious mastication exercised by primitive races now or recently living.[10] Among some of these mastication has been promoted almost to the position of an industrial art.

The chewing of very tough substances in order to extract therefrom liquid or nourishment.--The recently extinct Tasmanians included among their articles of diet a species of sea-weed which, even when cooked, was so tough as to require long-sustained mastication in order to extract its nutrient elements. The Indians of North California chew kelp, which is "as tough as white leather" (_i. e._, leather dressed with alum). "A young fellow with good teeth will masticate a piece of it a whole day." Again Featherman[11] tells how when the Bushmen are short of food in the winter they steep an old dried gnu-skin in water and, having rubbed off the hair, boil it, and proceed to gnaw the tough morsel until their very jaws ache. The Modoc Indians are said to munch the raw kais root all day long.[12] Among the Esquimaux it is a universal custom to chew the raw skin of the whale, the porpoise, and the seal for the blubber it contains, and the skin being as tough as india-rubber, it requires, as may be imagined, a good deal of chewing. The Lower Californians also chew deer-skin and ox-skin (Bayert). The more southern Esquimaux, according to Nansen, preserve the stalks of _angelica_ by steeping them in a mixture of chewed blubber and saliva. Finally, I may refer to the habit of chewing the sugar-cane, a practice which is prevalent among the natives in all countries where the cane grows, and affords, it need scarcely be said, abundant exercise for the jaws and teeth.

Mastication in the preparation of beverages.--I find that among widely separated aboriginal peoples chewing is resorted to in the preparation of beverages, both intoxicating and non-intoxicating. The Gran Chaco Indians make an intoxicating drink by chewing the algarroba bean and then spitting into a receptacle. In other parts of South America berries are chewed with the same object. In some of the Pacific Islands boys and girls with good teeth are selected to chew a root (kava), from which they then prepare a drink. In New Guinea drinks are similarly prepared from roots. Boiled cassava root is chewed by the Indians of Nicaragua for the same purpose. In British Guiana the natives make a drink by adding chewed maize and saliva to sweet potato, maize, and sugar-cane. The Indians in Honduras, after steeping cassava cake or carbonised bread in hot water, chew a portion and mix it with the rest.

Mastication in the industries.--Even among moderns teeth are used for many purposes other than mastication--_e. g._, for holding pins and needles and for severing cotton; also in some industries--_e. g._, among diamond workers--where it is the custom for girls to hold the diamond between their front teeth, which in consequence get much worn away, as I have myself seen. It is only among primitive peoples, however, that the jaws and teeth actually play the part of implements for use in the arts. The Australian women make lines, nets, and bags by chewing various kinds of fibre, a process which wears down their teeth considerably and may cause them to be tender.[13] The Esquimaux are still more dependent upon the use of their teeth as implements, especially in the preparation of skins for their clothing, boats, and lines. The teeth are used to hold the skins, while the latter are being scraped, the mouth constituting, in fact, "a third hand;" and the front teeth of Esquimaux women are often by this means worn away to the merest stumps.[14] The garments of the Esquimaux, even to the boots, are made up of skins which have been laboriously chewed for this purpose by the women "inch by inch," till they acquire a beautiful softness and flexibility, and are often, indeed, chewed

again after having been dried. And we are told that the women have no objection to the task, while the children are eager to help in it on account of the blubber the skin contains; also, that in bad times the men do not object to join in the work. The lines for harpooning are prepared in a similar way from the skin of the bearded seal, and in very large quantities.[15] When we think of the quantity of skins needed for these lines, for their dress, including boots and gloves, and for their boats (although for the latter some skins are used without having first undergone chewing), it is clear that enormous quantities must be chewed. The Esquimaux men also use their teeth considerably in other work--_e. g._, in lashing the sledges together.[16] The Indians of North California use their teeth for stripping the bark from the fresh shoots employed in making their wickerwork utensils, and they also employ their teeth in making strings, cords, and nets.

THE INSTINCT TO MASTICATE

Seeing that the maxillary apparatus of man has for long ages past been put to vigorous use, it is not surprising that the need to exercise it should express itself as a powerful instinct. This instinct manifests itself in many and curious ways, some of which I will now consider. During the early months of life the natural function of feeding at the breast provides the infant's jaws, tongue, and lips with all the needful exercise. This bottle-feeding fails to do, and we frequently find bottle-fed children seeking to satisfy the natural instinct by sucking their thumb, fingers, or any convenient object to hand. The teeth are a provision for biting hard foods, but even before they actually appear we find the child seeking to exercise his toothless gums on any hard substance he can lay hold of, and there can be no doubt that exercise of this kind tends to facilitate the eruption of the teeth, a truth, indeed, recognised universally, whether by the primitive mother who strings the tooth of some wild animal round the neck of her infant, or the up-to-date parent who provides her child with a bejewelled ivory or coral bauble. When the teeth have erupted, the masticatory instinct finds among primitive peoples abundant satisfaction in the chewing of the coarse, hard foods which constitute their dietary; but among us moderns, subsisting as we do mainly on soft foods, affording but little exercise for the masticatory apparatus, it does not find its proper expression, and thus tends to die out. Nevertheless, it dies a hard death, and long continues to assert itself; witness the tendency of children to bite their pencils and pen-holders; I have known a child to gnaw through a bone pen-holder, much in the same way as a carnivorous animal gnaws at a bone.

This instinct to chew for chewing's sake manifests itself all over the world. In our own country not only do children bite pencils and pen-holders, but they will chew small pieces of india-rubber for hours together. The practice of gum-chewing, so common among our American cousins, evidently comes down from far-off times, for the primitive Australians chew several kinds of gum, attributing to them nutrient qualities,[17] and the Patagonians are said to keep their teeth white and clean by chewing _matri_, a gum which exudes from the incense bush, and is carefully collected by the women and children.[18]

A widespread custom in the East is betel-chewing, which is met with in India, Malay, Melanesia, and Polynesia, and even among the primitive Veddahs of Ceylon. This article is composed of the pungent leaf of the betel plant, the areca nut and lime rolled together, and when chewed yields a reddish juice which stains the mouth and teeth. The Veddahs, failing to get the genuine article, manufacture a quid from the leaves of an aromatic plant, the barks of one or two kinds of tree, and calcined small shells.[19] The compound must possess some strange attraction, for otherwise such pains would not be taken to secure it. What is the attraction? Doubtless betel has stimulating properties, and it must, moreover, be remembered that the mere mechanical act of mastication stimulates the circulation, a fact which helps to explain the tendency for man, all the world over, to chew non-nutrient substances. Tobacco-chewing is common in many parts of the world, and here, again, the effect for the time is stimulating. Pitcherie is extensively chewed among the aboriginal Australians; it consists of twigs of about the thickness of rye-grass stems, which are first chewed into a mass, then mixed with the ash of gum trees, and made into a paste, which is chewed for its stimulating and narcotic effects.[20]

I may allude in passing to the grinding of the teeth, which takes place during sleep in disturbed states of the nervous system. It is a true masticatory act, in which the normal lateral movement of the mandible is well marked, and it may thus be regarded as a perverted manifestation of the masticatory instinct.

THE CAUSATION OF INEFFICIENT MASTICATION

The effects for good upon the organism of efficient mastication being profound and far-reaching, it follows that inefficient mastication must lead to many evils. What these are we have now to consider; but first it will be well to inquire into the causes of the defective mastication which prevails among moderns.

1. _Softness of food._--By far the most important of these lies in the nature of the food taken. The food of to-day--of the late agricultural age period, as I have termed it--is for the most part soft and pappy, of a kind which does not compel thorough mastication; so much so, indeed, that, as I have already said, we may speak of this as the age of pap. This feature is especially noticeable in the case of children's diet: under the modern system children are kept on a liquid, or semi-liquid, diet, not merely during the first months, but during the first years of life, and at the seventh or eighth month all kinds of artificial saccharide foods in liquid or semi-liquid form are poured into the child's stomach; thereafter he is fed on such viands as mashed potatoes and gravy, rusks soaked in milk, milk puddings, bread dipped in bacon fat, pounded mutton, thin bread-and-butter, and the like; and we are told that this is the kind of diet best suited to the young human, from the time of weaning to the end of the second year! The same pernicious methods are adopted subsequently. "Perhaps the great majority of children after they have got their complete set of temporary teeth have," writes Dr. Sim Wallace,[21] "a dietary such as the following. Breakfast: bread-and-milk or porridge, milk, tea, coffee, or cocoa, bread-and-butter, perhaps an egg. Dinner: potatoes and gravy, or meat, milk pudding. Tea: milk or tea with bread-and-butter, jam, cakes. Supper: bread or biscuit and milk." Now food of this kind does not invite mastication, and it finds its way into the stomach all too readily. Hence the instinct to masticate has little opportunity of exercise and, not being properly exercised, tends, as I have said, to die out. Small wonder that the child nourished on such pappy food acquires the habit of bolting it, and learns to reject hard, coarse foods in favour of the softer kinds; everything nowadays must be tender, pultaceous, or "short." Given a choice between a food compelling little or no mastication and one necessitating prolonged mastication--as between, say, fresh Vienna bread and an Abernethy biscuit--and in nineteen cases out of twenty the one which gives the least trouble in eating will be chosen. To such absurd lengths has this harmful custom been pushed that even bread crust is avoided by many. Witness the fashion of eating bread-and-butter with a minimum of crust; order bread-and-butter at any place of refreshment, and the last thing you will be served with is a plateful of crusts of bread. Many establishments, indeed, make a regular practice of giving away their crusts as unsaleable. Thus, the rectangular loaves used for bread-and-butter in the "Aërated bread-shops" are cut transversely into slices, each loaf thus yielding two end crusts which are put into baskets for the poor, only the soft crumby pieces being reserved for the customers, to be, in due course, no doubt washed down by copious libations of tea and coffee.

When we trace the diet of the modern from childhood upwards we find the same story: it tends to remain soft and pappy to the end. Animal food, especially as it comes to the tables of the well-to-do, necessitates very little mastication. It is the coarser varieties of vegetable food alone which call out the full functional activity of the masticatory apparatus, but the vegetable food of to-day is rarely of a kind to do this; cooked vegetables, such as potatoes, greens, peas, and beans, can be, and generally are, swallowed after little or no preliminary mastication, and our flour is so carefully deprived of its fibrous portions and so cunningly dealt with in the bakehouse and kitchen in the making of bread, cakes, and pastry which shall eat light and short that these articles get very little chewing; while such vegetable products as rice, vermicelli, tapioca, and macaroni are, as served at table, so soft that they slip down into the stomach almost as readily as simple milk. Let any one run through his dietary of any one day, and he will realise how very little work his masticatory apparatus is called upon to perform. It will read something like the following. Breakfast: porridge and milk, eggs, bacon, bread, and marmalade. Lunch: fish, tender meat, boiled vegetables, bread, some "sweet," and cheese. Tea: bread, butter, and cake. Dinner: much the same as lunch. What opportunity, I ask, does such a bill-of-fare afford for the development of teeth and jaws, and for the proper functional activity of the salivary glands?

2. _Defective masticatory apparatus._--Another potent cause of inefficient mastication is some defect in the masticatory apparatus, and defects of this kind are very common in those who have not been accustomed to masticate thoroughly in early life. Foremost among these are irregularities of the teeth leading to faulty "bite" and caries of the teeth which causes them to be tender or to break away, if it does not lead to their actual extraction. Mastication cannot be thorough where the bite is defective, for this not only leads to imperfect opposition of the upper and lower teeth, but renders the lower ones incapable of that ample lateral movement, against the upper which is needful to normal mastication.

3. _Idiosyncrasy._--Some are temperamentally more disposed to hurry over their meals than others. The katabolic, restless, nervous individual is more apt to swallow his food hastily than is his more deliberate and phlegmatic brother. Individual differences in this respect are even observed among the lower animals. Thus, one of a pair of horses of about the same age and build is nervous and excitable and inclined to bolt its food, while its companion of more stolid temperament is a thorough and efficient masticator. The former shows comparatively little wearing down of the teeth, and often suffers from indigestion, a large portion of corn grains passing through his digestive canal intact; in the latter the teeth are well worn, indigestion never occurs, and but very few grains pass through the digestive tract unchanged. It may be objected here that we cannot help temperament, and to a large extent this is true; but much can be done towards modifying it, and it is something to know where dangers, temperamental dangers, among others, lie.

4. _Circumstances of life._--Again, in this hurrying, strenuous age people are much less deliberate than in the easy, slow-going days of long ago. A meal is too often regarded as something to be got through quickly, as taking up time which might be devoted to something more profitable. Especially is this true of breakfast and lunch; it is no uncommon thing for a business man to hurry through his breakfast in a few minutes, preparatory to rushing off to his train, and his lunch as likely as not is as hastily swallowed in his office or at a bar. Tradesmen are apt to take their meals in mere snatches; apprentices, shop girls, and other “hands” are often not allowed sufficient time for their meals; while, to come to the professions, we all know how the busy medical man, for instance, is often obliged to take a hurried snack in the short intervals between seeing his patients. No wonder that thus circumstanced people acquire the habit of bolting their food. A meal should be regarded as an end, and an important end, in itself. It should be taken at leisure, body and mind being, for the time being, given up to it, and to agreeable social intercourse. If this rule were always observed a most important source of inefficient mastication would be removed.

SECTION III. From _London Lancet_, July 25, 1903

EVILS RESULTING FROM INEFFICIENT MASTICATION

Too much food is eaten.--Inefficient mastication conduces to excessive eating. Now it is obvious that soft foods, and these constitute the bulk of our modern dietary, pass much more readily into the stomach than coarse, hard foods which compel a certain amount of preliminary mastication, and for this reason the former predispose to excessive eating: hence a danger at all periods of life, not only in grown-ups but in children, even infants; brought up as the latter are, mainly on liquid and pappy foods, many of them consume not only far more than is needful, but far more than is healthful, their stomachs being literally deluged with nutriment.

When the food is of a kind necessitating abundant mastication it is much less likely to be taken in excess, for the longer the time spent in mastication the less will the individual be tempted to consume; even in the case of soft food, less will probably be eaten if it be thoroughly masticated and insalivated than if it be bolted. Thorough mastication, however, not only tends to diminish the amount of food consumed on account of the time and labour which it entails; it actually reduces the amount needful to constitute a sufficiency, for the more perfectly the food is chewed the more perfectly is it digested and the more economically is it disposed of in the system; the less, moreover, is the tendency to that morbid craving for food which is so frequent an accompaniment of defective digestion. It is certain that appetite and the needs of the system are sooner satisfied when food is well masticated and digested than when it is swallowed whole.

A mass of unmasticated food may lodge in the throat and cause fatal suffocation.--This may seem to be a very exceptional kind of evil, but I am informed by one whose experience makes him an authority on the ways of the British soldier that it is by no means uncommon for soldiers in barracks to die from this cause. Usually it is when they are under the influence of alcohol that fatal results occur, post-mortem examination disclosing large undigested masses of food in the stomach. A like experience is also frequently met with in the case of men killed by accident.

The presence of masses of imperfectly masticated food in the stomach may cause disturbance either mechanically or by reason of their imperviousness to the gastric juices.--We have already seen that the digestibility of a food is largely determined by its consistence, and that many articles of diet, such as cheese, hard-boiled egg, cocoa-nut, lobster, and new bread, which have the reputation of being very indigestible, can, if finely comminuted by chewing or otherwise, be rendered quite digestible. Such articles are indigestible essentially by reason of their compactness; the compact lumps, but little pervious to the gastric juice, tend to undergo abnormal chemical change in the stomach, and may in this way cause violent local irritation, even to the extent of setting up acute gastritis; or they may paralyse the nerves of the stomach and check gastric secretion and movement, and thus remain _in loco_ wholly undigested for hours or even days; or, again, more distant nervous effects may be produced, such as frontal headache, which may be felt almost immediately after ingestion of the peccant substance, being of reflex rather than toxic origin, and presumably in some cases, at least, due to the mere mechanical irritation of the stomach. The passage of imperfectly digested food into the bowel may still further aggravate matters. It does not seem improbable that the habitual bolting of food, by the prolonged local irritation to which it gives rise, may predispose to cancer of the stomach: Napoleon was a notorious fast eater and it is well known that he died from this disease.

While, however, the bolting of food readily sets up disturbance in some, it must be conceded that in many it seems to cause little or no inconvenience; especially is this the case in the young with vigorous muscular stomachs capable of triturating the food, and thus doing duty for the teeth. The human stomach is, indeed, a long-suffering organ, and wonderfully tolerant of ill-treatment, sometimes almost rivalling in its hardiness the gizzard of the bird. Nor is this surprising when we reflect that it is, in the ordinary course of

nature, constantly exposed to the entrance of noxious substances. In this respect it stands in marked contrast to the intestines, for not only are highly irritant substances often vomited rather than passed onwards, but in ordinary circumstances the gastric contents are not allowed to pass the pylorus, until they have been duly prepared by the stomach; the pylorus, in fact, stands guard over the entrance to the bowel and is jealous of anything passing it which is likely to injure that canal.

And just as the pylorus protects the bowel so, in exceptional cases, may the œsophagus protect the stomach, regurgitating, after the fashion of the ruminants, insufficiently masticated bits of food, in order that they may be re-masticated. I have myself met with cases in point. Sometimes, in cases of this kind, the œsophagus may be dilated into a sort of proventriculus, which is capable of temporarily lodging a large quantity of food. Such a proventriculus is said to have developed in an apprentice who, not being allowed sufficient time for his dinner, rapidly bolted it, to regurgitate it after working hours and to chew the cud at leisure. Whether in these cases the food is ever returned from the stomach itself I am unable to say.

While the stomach is the organ especially liable to be injured by the swallowing of lumps of unmasticated food, the bowel may also suffer, especially the cæcum and vermiform appendix. And here we come to one of the most serious indictments against the bolting of food; though man has doubtless always suffered from appendicitis, there can be little doubt that this malady is more common now than it used to be; and there is equally little doubt, in my own mind at least, that the cause of its greater frequency is related to his food. I do not propose to discuss here in detail how food is capable of causing appendicitis, but will merely refer to one of the ways in which it may do so. I had already come to the conclusion that the habit of bolting food is a potent cause, when I read Sir Frederick Treves's Cavendish Lecture in which he makes that contention. Sir Frederick Treves points out that in this rushing age people, especially business men, are apt to hurry over their meals and to take them at irregular times and often while standing at a bar; even when there is more leisure, food is rarely masticated nowadays in the same thorough way that it was in the old time, when it was of a coarser nature: hence solid lumps, especially in the case of such articles as pine-apple, preserved ginger, nuts, tough meat, and lobster, are apt to pass beyond the pylorus and, escaping intestinal digestion, to lodge in the cæcum and precipitate an attack of appendicitis, the most common predisposing cause of which is a loaded cæcum, often preceded by constipation. Sir Frederick Treves contends that this distended state of the cæcum encourages catarrh of the appendix by dragging upon it and blocking its orifice, as well as by twisting it and thus interfering with its blood-supply.[22]

An excess of starch is apt to pass into the stomach.--We have just seen that inefficient mastication tends to promote over-eating, and what has been said on this head applies to all kinds of food, starchy foods among others. It leads, however, to a further evil as regards these latter; not only does it tend unduly to increase the quantity of them consumed, but it too often causes the stomach and intestines to become flooded with starch in a wholly undigested form. I cannot too frequently repeat that in ancient times, especially in the pre-cooking age, laborious mastication was needed in the case of all starchy foods, partly because they were coarse and fibrous, but chiefly because the starch and other nutritive ingredients had, in order to become available for nutrition, to be liberated from their undigestible cellulose envelopes. In these days of prepared, soft, starchy foods, however, mastication is very little required for these purposes, but in other respects it is as needful as ever, indeed more needful, if the large quantities of starch which are now consumed are to be insalivated effectually. The laborious and sustained mastication to which primitive man was compelled to subject _his limited supplies of uncooked starchy food, went far to effect complete digestion of the starch within the mouth_, for raw starch is freely digested by the saliva,[23] and hence in his case _very little passed into the stomach in a wholly undigested form_. How different is the case with us moderns. Since the opening of the era of agriculture and cooking, man has enormously multiplied his supplies of saccharide, and he now consumes large quantities of starch which has been freed from its cellulose framework by cooking, milling, grinding, and the like, and reduced to a soft or pappy form, such as milk puddings, porridge, boiled potatoes, and new bread, all of which can be swallowed with little or no preliminary chewing; and when food can be swallowed easily, without mastication, few will take the trouble to masticate it. In these circumstances the starch does not undergo adequate salivary digestion, and a large quantity passes wholly undigested into, and out of, the stomach, not beginning to be digested until it reaches the bowel. Small wonder that the latter should rebel again this invasion and that flatulence, pain, and other dyspeptic evils should result.

It is especially in young children that these evils are observed. Too often the stomach of the child, semi-carnivorous, remember, by its ancestry, is literally deluged with pure starch. At the seventh or eighth month, or even earlier, for many of the patent infant foods contain it, this substance is poured into the stomach without being afforded any opportunity of undergoing salivary digestion; and for a long time after infancy large quantities are given in the liquid or pultaceous form, such as rusks soaked in milk, puddings, and mashed potatoes. This practice of deluging the digestive organs with starch, besides leading to the more immediate troubles connected with flatulent dyspepsia, gives rise to abundant formation of toxins which, by irritating the alimentary mucous membrane,

set up gastro-intestinal catarrh; this, again, intensifies the dyspepsia already existing and causes a still further production of toxins, so that the motions become intensely fœtid. These poisons being absorbed into the blood the tissues become saturated with them and the nutrition of the entire organism is disturbed, the faulty metabolism manifesting itself by a diminished resistance to pathogenic agencies, by a tendency on the part of the tissues to inflame (as shown by a liability in children thus fed to bronchitis, rhinitis, naso-pharyngitis, and tonsillitis), by their proneness to tuberculosis, and finally by a disposition to rickets, which I little doubt is essentially of toxæmic origin.

Besides the above-mentioned troubles an excess of starch in the stomach may set up hyperchlorhydria--_i. e._, that form of dyspepsia in which there is excessive secretion of hydrochloric acid. This affection occurs during the most vigorous years of life and is apparently due to excessive activity on the part of the gastric glands. The excess of acid does not give rise to any symptoms so long as there is any unsatisfied proteid in the stomach to unite with it, but directly all the proteid is satisfied and free acid is present in the stomach, pain, heartburn, and distention are apt to be felt; hence these symptoms are generally removed temporarily by a meal, the food ingested seizing upon the free acid, and tend to recur in the course of an hour or two. Other symptoms are mental and bodily lassitude and great mental depression, while, if the condition is long-continued, gastric catarrh and dilatation ensue. Eructation of the acrid mass, its removal with a tube, or its dilution or neutralisation by an alkali, causes relief of the symptoms. Now Dr. William Russell, who has recently studied this form of dyspepsia, has shown, and the fact is most significant from our present point of view, that in it starch is the last constituent to leave the stomach; that when this organ has so far emptied itself as to contain but one or two ounces of very acrid material the residue consists chiefly of finely divided undigested starch, which continues to stimulate the gastric secretion; “and, there being no more proteid with which to combine, the secretion accumulates and leads to hyperacidity.”[24] Inasmuch, then, as inefficient mastication leads to an excess of starch in the stomach, we see how it may predispose to hyperchlorhydria and we shall presently see that there is yet another reason why it should do so.

It will be gathered from the foregoing that thorough mastication is the most effective way of securing efficient starch digestion. This simple fact has been most strangely overlooked. Thus “van Valzah considers that not a little of the difficulty of the digestion of starches and cereals can be overcome by more thorough cooking. Patients who cannot eat potatoes after ordinary cooking are [he urges] often able to digest them very readily if they are doubly cooked before being served. Cereals, as a rule, should [he contends] be allowed to simmer all night and then be thoroughly cooked for a half hour in the morning before being eaten.”[25] This is an admirable illustration of the modern tendency to cheat the mouth of its proper work. A much more rational way of facilitating starch digestion in those who experience a difficulty in this respect is by efficient mastication.

Evils resulting from an insufficient quantity of alkali in the stomach.--I doubt if it is adequately realised what a large amount of alkaline saliva passes into the stomach as the result of prolonged mastication. Its presence there serves the useful purpose of prolonging the period of starch digestion within the stomach, while it further aids gastric digestion not only by exciting the secretion of gastric juice, but also by its influence on the reaction of the gastric contents; it can scarcely be doubted that the effect is on the whole one favourable to digestion in general. We have just seen that defective mastication may predispose to hyperchlorhydria by allowing an excess of pure starch to pass into the stomach, and I suggest that it may further operate in the same direction by cheating the stomach of its due supply of alkaline saliva. Now the saliva in this affection is apt, as was pointed out by Sir William Roberts, to be superalkaline, and for this reason he recommended his acid-dyspeptics to excite the flow of it by chewing gum-mastic with the object of neutralising the gastric hyperacidity. That relief can thus be obtained there can be no doubt; but it is surely more rational to get the patient to stimulate his salivary glands by masticating actual food, by which we secure the additional advantages accruing from its complete insalivation and comminution as well as from the reflex gastric effects. Actuated by these considerations, I have long been in the habit of recommending hyperchlorhydriacs to subject their food to prolonged mastication, this being, in my belief, the most rational and effective way of breaking the stomach of its vicious habit. In extreme cases we must insist that each morsel of food should be chewed at least one hundred times and not permit any relaxation of this severe discipline, until the stomach has been schooled into healthier ways. _Evils in connection with the jaws and their appendages and the adjacent structures: the nasal passages, naso-pharynx, and faucial tonsils._--In those who do not masticate properly in early life these parts fail to develop as they should, and they are on this account alone predisposed to disease; their resistance to disease is still further lowered by the fact of their blood and lymph flow not being adequately stimulated by the vigorous exercise of the masticatory muscles. Now we have seen that the great cause of defective mastication in children is the softness of the food given them and that the feeding of them upon an excess of soft food, especially the starchy kind, disturbs digestion, induces toxæmia, and in this way evokes a catarrhal tendency. In children thus fed we have therefore several conditions which make for disease in the parts under consideration--defective development, sluggish circulation, and toxic saturation. Is it any wonder that the modern child should be liable to disease in these regions, that he should so frequently suffer from rhinitis, naso-pharyngitis, tonsillitis, and from hypertrophy

of the pharyngeal tonsil (“adenoids”) and of the faucial tonsils?

It is in this way that I would explain the frequency of adenoids among the children of civilised communities. I claim, in fact, that this disease is largely dietetic in origin. I submit that a child whose nasal apparatus and naso-pharynx are well-grown and habitually bathed by a stream of pure blood and lymph, periodically accelerated by an ample and vigorous use of the masticatory muscles, is unlikely to contract adenoids. On the other hand, I contend that a child in whom these parts are ill-developed and bathed by an habitually sluggish stream of tainted blood and lymph--one, _i. e._, that is not only poisoned, but rarely, if ever, hurried along its lazy course by due exercise of the muscles of mastication--I submit that such a child runs great risk of contracting the disease. The influence in setting up adenoids of toxic saturation with its resulting catarrhal tendency is shown by the frequency with which this affection follows upon the rhinitis and naso-pharyngitis of measles and diphtheria, and in order to realise how greatly the circulation of blood and lymph in the walls of the naso-pharynx must be influenced by mastication, one has but to remember how very closely the pterygoids are related to this region; in exploring it for adenoids they can, indeed, often be felt to stand out prominently.[26]

This, then, is my explanation of the truly fearful prevalence of adenoids among the moderns. It is essentially a disease of pap-fed peoples. A child may, with the one exception that he is fed on a pappy, super-saccharide diet, be brought up under ideal health conditions. He may live in the heart of a dry, open country, far from the darkness, dust, and tainted atmosphere of the town, sleep with the windows open all night, live out of doors all day, be fed on the most nourishing (too nourishing, it may be) food, be clothed after the most approved methods, and yet, in spite of all this, we may find his naso-pharynx packed with adenoids. This disease is, in fact, scarcely less prevalent in the country than in the towns, scarcely less common among the rich than among the poor. Yet in primitive communities it is practically unknown. And what, I would ask, is the one condition in the material environment of my supposititious child differing from that of the primitive child? What but the factor of diet? Therefore, I say, the prevalence of adenoids among moderns must be the result of the modern system of feeding children, and the defective mastication which goes along with it.

That the foregoing is a grave indictment against that system, it need scarcely be said. For adenoid disease is fraught with many evils, among them mental hebetude, blocking of the Eustachian tubes, and manifold other auditory troubles, gastro-intestinal disturbances from the passage into the stomach of unhealthy discharges, and, most serious of all, nasal obstruction and consequent mouth-breathing. So serious are the evils connected with this latter habit that they demand more than a passing reference. Pronounced adenoid disease is always associated with mouth-breathing, and there can be no doubt that in the majority of these cases, the nasal obstruction is not in the nasal passages primarily, but is due to a blockage of the posterior nares by the adenoid growths, for it generally happens that nasal breathing is rapidly re-established after their removal, though in a certain proportion of cases the obstruction still persists, and has to be dealt with by treatment directed to the nasal passages themselves. Some have, indeed, contended that a primary nasal obstruction is one important factor in the induction of adenoids, leading as it does to a dry-cupping of the naso-pharynx during inspiration and to a consequent congestion of its lining membrane. I am quite ready to allow that this mechanism may play some part in causation, and such an assumption is in entire harmony with my main contention that adenoid disease is of dietetic origin, for nasal obstruction in children, other than that caused by adenoids, is mainly due to defective development of the nasal passages coupled with inflammation of their lining membrane, both of which conditions may, as we have seen, be essentially the outcome of defective diet.

Coming now to the evils resulting from mouth-breathing, we have first to remember that normally the air is inhaled through the nose, and is thus warmed, moistened, and filtered before being allowed to pass into the lungs; but in the mouth-breather the air, which may be dry, cold, and dust-laden, passes at once unprepared through the mouth into the lungs, impinging in its passage against the pharynx, thus drying and mechanically irritating the mouth, pharynx, larynx, and bronchial tubes, all of which are thereby predisposed to disease. In this way laryngitis and bronchitis, nay, even phthisis, may be induced. Dental caries is also predisposed to by the habit of breathing through the mouth. Mouth-breathing further interferes with the proper development of the cranial bones, but especially of the maxilla, giving rise to what may be termed the “mouth-breather’s jaw,” so characteristic is it I do not propose to discuss here the mechanism by which this deformity is produced, interesting though the question is; suffice it to say that nasal breathing is essential to the normal development of the jaws. The deformity in question, though it involves the maxilla chiefly, affects also the mandible from the fact of its being, to a large extent, moulded on the maxilla; in typical cases the maxilla is small and its alveolar ridge does not attain its normal length, but is compressed laterally towards the sagittal plane, giving rise to the false appearance of a “high arch” and often thrusting the anterior portion of the ridge forwards; the teeth, the growth of which is not so much interfered with as that of the imbedding bone, are thus prevented from taking up their proper positions and show irregularity, sometimes extreme. Dental irregularity may also, as we shall see, result from inadequate use of the jaws in mastication,

but not to the extent which is frequently observed in the mouth-breather's jaws, and therefore pronounced dental irregularity always shows that there has been protracted nasal obstruction, and this in the vast majority of cases implies the existence of adenoids, past or present; I say in the "vast majority," for in a few rare cases long-continued nasal obstruction in children originates primarily in the nose and may lead to the typical mouth-breather's jaw, with the resulting dental irregularity.

The tongue.--If the tongue is not properly exercised in childhood and youth, we find it imperfectly developed; hence in inefficient masticators it is generally small. It must not be forgotten in this connection that this organ is considerably exercised when the infant is at the breast, from which the milk is obtained, not by suction, but by a vigorous tugging and squeezing of the nipple (in which the tongue takes considerable part), whereby the gland is reflexly excited to secrete. When, on the other hand, the child feeds at the bottle he obtains his milk by actual suction, and generally through an orifice of such ample dimensions as to allow the bottle to be rapidly emptied with comparatively little exercise of the lips and tongue. In short, the breast-fed infant has to do some work for his living, and that of a sort calculated to promote the health of the jaws and their appendages, while the bottle-fed child can glut himself by doing very little more than opening his mouth; wherefore we find the tongue and adjacent parts less developed in the latter than in the former. It may be thought to be a matter of indifference whether the tongue develops to its normal proportions or remains small, but such is by no means the case, for, as Dr. J. Sim Wallace has shown, the pressure of this structure against the teeth promotes the normal development of the jaws, especially of the mandible, and when it is small they are apt to be so too.

The salivary glands.--Just as mastication increases the functional activity of the salivary glands and buccal glands and favours their normal development, so, contrariwise, inefficient mastication during early life fails to call forth their normal functional activity and to secure their adequate development. Thus we find that a child who has been brought up on hard, starchy foods, necessitating abundant mastication has much larger and more active salivary glands than one who has been fed on soft foods which slip down into the stomach before they have had the chance of being properly masticated, and it is needless to say that the more efficient these glands are the more likely is digestion to be carried out satisfactorily.

The jaw-bones.--If the jaws are not adequately exercised in youth by mastication they fail to grow to their normal size and shape, and there is apt in consequence to be overcrowding of the teeth. The main defect of the jaws in such cases is their smallness; they do not present that pronounced lateral compression and anterior protrusion which characterise the mouth-breather's jaw, nor such extreme dental irregularity, the most common being overlapping of the incisors, displacement of the canines, and difficulties in regard to the eruption of the wisdom teeth from shortness of the alveolar ridge. I have already referred to the progressive shortening in the post-molar ridge, which has been taking place during man's evolution from the anthropoid in correspondence with the alteration in his diet.

We thus see that defective use of the jaws leads to irregularity of the teeth (1) directly and (2) indirectly through the induction of adenoids. This irregularity is not only unsightly but leads to certain evils which thus primarily owe their origin, in large measure at least, to defective mastication. What, then, are these evils? In the first place, dental irregularity predisposes to dental caries by favouring the lodgement of food between the teeth; in the next place, it leads to defective "bite." Now when the bite is defective adequate mastication is impossible, for not only is it impossible in these circumstances to oppose the teeth properly, but also, owing to their interlocking, to accomplish that free lateral movement of the lower teeth against the upper, which belongs to normal mastication. I do not say that defective bite is the sole cause of this imperfect lateral movement; it may, indeed, be observed in most moderns brought up on soft pappy food, whether the bite be good or not. Normal mastication is, in fact, becoming a lost art; the average modern masticates mainly by a vertical compression of the lower teeth against the upper, and in only a small degree by a lateral frictional movement which, it is needless to say, is the more effective method for grinding purposes; and it is, I doubt not, chiefly for this reason that the teeth of modern man are so much less worn down than those of primitive peoples.

The teeth.--Imperfect use of the teeth leads to many ills. When adequately exercised and made to execute for one or two hours every day a lively dance in their sockets, during which the circulation of blood and lymph in the tooth-pulp, periodontal membrane, and surrounding tissue of the gum is vigorously stimulated, and the cavity of the mouth is bathed in a copious flow of salivary and other buccal secretions, we have conditions which make alike for the health of the buccal mucous membrane, of the teeth, and of the periodontal membrane and alveoli; but when the circulation is not duly stimulated in this way the teeth do not develop properly, while the secretions of the mouth are apt to be scanty and unhealthy, both of which conditions predispose to caries. How far dental caries is due to inherent dental weakness and how far to faulty conditions outside the teeth we need not stop to inquire; Dr. Wallace attributes little influence to the former factor, contending that caries depends essentially upon faulty dental environment; and one can scarcely doubt that the state of the gums and of the oral secretions profoundly influences the growth of bacteria in the mouth, upon the acid yielded by which organisms the corrosion of the dental enamel essentially depends. Faulty conditions of the oral

secretions likewise favour the deposit of tartar.

Another result of imperfect use of the teeth is undue thinness of the alveolar walls and periodontal membrane, in consequence of which the teeth are not so firmly held in their sockets as they should be. This is, I believe, one of the reasons why they are prone to fall out prematurely among the moderns: we know that the teeth tend to drop out in old people owing to a senile atrophy of the alveolar walls; the Haversian canals get smaller and may, indeed, disappear entirely, and it stands to reason that this atrophy must be hastened by inefficient exercise of the teeth. So far as I am able to gather from an examination of skulls in museums, the teeth are rarely shed among primitive peoples before extreme old age, while among moderns they frequently fall out long ere this is attained.

A still worse evil attaching to insufficient use of the teeth is pyorrhœa alveolaris or Riggs's disease, which, in conjunction with the deposit of tartar, is the great cause of the premature loosening and shedding of the teeth observed among latter-day civilised peoples. This affection consists of a purulent inflammation of the periodontal membrane, owing to the invasion of it by pyogenic cocci, so that pus wells up on pressing the gum against the teeth. Now, when by a vigorous use of the teeth the buccal cavity is kept well flushed with healthy secretions, the growth of micro-organisms within this chamber is kept down, and when, by the same means, the vitality of the periodontal membrane and adjacent tissues of the gum is periodically stimulated, these tissues offer stout resistance to the invasion of pathogenic organisms; but when, contrariwise, the teeth are little used, the secretions of the mouth are in consequence defective both as to quality and quantity, and the growth of organisms in the buccal cavity is promoted; and when, further, the circulation in the periodontal membrane and adjacent soft tissues is not adequately stimulated by vigorous mastication, their vitality is poor and they offer but a feeble resistance to parasitic invasion. We can thus, I think, safely infer that inefficient mastication is a potent cause of pyorrhœa alveolaris; and the chief cause of inefficient mastication being the eating of soft foods, we must also conclude that the latter practice is chiefly responsible for the disease in question; such foods further predispose to this affection in that they are apt to lodge between the teeth and by undergoing decomposition there to favour the growth of micro-organisms within the mouth. The condition of the teeth and gums among the civilised poor is, alas, little calculated to make us proud of our boasted civilisation--the spongy pus-exuding gums, the lengthening, loose, tartar-covered, carious teeth, and the putrescent breath constitute a damning indictment against our modern system of living on a soft, pappy diet, and not giving the teeth the work for which they are designed. I never examine such a mouth without being impressed with, and I may add oppressed by, this fact.

I am not, of course, contending that pyorrhœa alveolaris only occurs in those who masticate inefficiently; whatever causes an unhealthy condition of the gums and saliva predisposes to it, but it is surely much less common in those who masticate well than in those who masticate ill. Confirmatory of this statement is the fact that it is more frequent in those with irregular teeth than in those with a good bite, who are thus able to put their teeth to more effective use. This affection is very common among the carnivora of menageries as well as among dogs and cats; indeed, one seldom fails to find it in dogs over four years of age, and in old dogs it is generally rampant. Doubtless in all these cases the general conditions of life play some part in the causation of the disease, but I do not think that we can eliminate from it the factor of defective use of the jaws and teeth, for it is certain that dogs and cats are fed largely on pappy foods and are often insufficiently supplied with bones.

The causation of dental caries.--Dr. Wallace, in his philosophical work on "The Cause and Prevention of Decay in Teeth," contends that the cause of the prevalence of dental caries is that the natural food-stuffs are, to a large extent, ridded of their accompanying fibrous parts and consumed in a form which renders them liable to lodge and to undergo acid fermentation in the mouth; while from the same cause and the induced conditions the micro-organisms of the mouth lodge and multiply and augment the rapidity and intensity of the acid fermentation. I am perfectly at one with Dr. Wallace in believing that the removal of the fibrous portions of food is the main cause of the prevalence of caries among moderns, and I can hardly doubt that foods so prepared tend to promote caries in the way indicated, but I venture to think that they do this even more by failing to call forth the normal degree of mastication. I cannot but think that if these same soft foods were as laboriously masticated as they would need to be if they retained their fibrous ingredients, dental caries would be much less common than it actually is. I have endeavoured to show how very different the local conditions are in the efficient from what they are in the inefficient masticator--how in the former the jaws and teeth are wont to be well developed, the bite to be good, and the secretions which bathe the teeth to be of a kind calculated to promote their health; and how in the latter an entirely opposite set of conditions is wont to prevail. That it is possible to maintain a fine set of healthy teeth till past middle life on ordinary civilised diet, provided the food be habitually subjected to efficient mastication, is shown in the case of the man already referred to, and by numerous other cases which I have observed.

Since the application of cooking to food there has been a progressive lessening in the work of the jaws and teeth and, parallel with this, a diminution in their size and an incursion of dental caries. Among the anthropoids in their natural state caries is practically unknown, and I think we may conclude that the same was true of man before he learnt to cook. In the pre-agricultural races, such as the aboriginal Australians, the effect of cooking the food is shown in the lessening in the size of the wisdom teeth and of the post-wisdom alveolar ridge; dental caries, though rare among these people, does occur, and especially in the wisdom teeth.[27] In the early agricultural period, owing to the increasing softness of the vegetable food, the jaws and teeth show a tendency to be smaller than in the previous periods; the wisdom teeth are decidedly smaller and more prone to caries, while caries of the other teeth is by no means rare. In the late agricultural period the jaws and teeth often show very decided defects of development, while dental caries is, as we know but too well, rampant.

What has been said concerning the relative prevalence of caries in different diet epochs applies to many other diseases of the teeth; thus, along with the increase of caries, there has been a parallel increase in the prevalence of pyorrhœa alveolaris.

CONCLUDING REMARKS

I have now set forth some of the evils resulting from inefficient mastication. They are many and serious. The immediate evils, such as over-eating, indigestion, adenoids, dental caries, and pyorrhœa alveolaris, are bad enough, but when we consider the secondary evils to which these primary ones give rise,--and I have only mentioned a few of them,--we must come to the conclusion that an appalling amount of misery and suffering may be saved by the simple expedient of inculcating the habit of efficient mastication. How this end can best be accomplished will be considered in the next section.

SECTION IV. From _London Lancet_, August 8, 1903

MEANS OF INSURING ADEQUATE MASTICATION

In order to secure the full advantages accruing from the use of the jaws and their appendages, it is, above all, necessary for them to be adequately exercised during the period of development. If this is done, not only will the tendency to dental caries, adenoids, indigestion, and other evils be greatly diminished, but the masticatory instinct will establish itself as a permanent force, so that the individual will tend for the rest of his life to subject even soft foods to thorough mastication. The tongue, the lips, and the jaws of the newly born child find their natural exercise at the mother’s breast, and we should, therefore, do our utmost to get the mother to suckle her child, the bottle affording neither the same kind nor the same amount of exercise. If, unhappily, we fail in this, we must see that the teat of the feeding-bottle is so constructed as to compel the child to earn his meal by, at any rate, some exercise. This kind of exercise promotes the growth of the tongue and thus of the jaws, especially of the mandible. Directly the infant shows a disposition to bite hard things the instinct should be gratified. We may observe a tendency in this direction as early as the third or fourth month, and it becomes more and more pronounced when, the time for the eruption of the teeth approaching, the gums begin to swell up and to get tender, and saliva begins to flow from the mouth; it is now, more than ever, necessary to provide the child with hard substances on which to exercise the jaws and the gums, and a great deal of the trouble of teething is due to the failure to recognise this fact. What, then, are we to employ for this purpose? I am convinced that it is a mistake to rely solely, or even mainly, upon baubles of ivory, coral, and the like useful though these may be in their way; it is far better to give the child something which is not only hard but nutrient and pleasant to the taste, something which will at one and the same time exercise the maxillary apparatus, excite the gustatory organs, and provide a certain amount of nutriment. To this end we may, as the teething time approaches, give a chop or chicken bone, from which most of the meat has been removed; by powdering the bone with white sugar or salt we may increase its attractiveness. From such bones a good deal of nutriment can be extracted, and this of a kind which is most acceptable to the infant stomach, for it must be remembered that the young human is in the main carnivorous. Indeed, since milk is a purely animal diet, all the mammals must be regarded as essentially carnivorous during the period of suckling, while man, as already observed, from the time he emerged from the anthropoid until he learned to cook his food, was throughout life mainly an animal feeder. Therefore we should not hesitate to allow the teething infant animal food in the form suggested. Chicken and chop bones, yielding as they do before the pressure on the gums, are, moreover, just of the right degree of consistence for the purpose in view, while they afford abundant exercise for the tongue; ivory, coral, and the like are, on the other hand, too hard and unyielding, and lack, moreover, the attractiveness belonging to sapidity.

By thus providing the maxillary apparatus with suitable exercise we shall do much to facilitate the eruption of the teeth and to favour the growth of the jaws and their appendages, including the salivary glands, and so to prepare the mouth for the reception of

vegetable food. This should, of course, not be given till the teeth appear. The order in which these make their appearance gives some indication as to the order in which vegetable food should be administered to the child. The first teeth to penetrate the gums are the lower incisors which appear from the seventh to the eighth month; then follow the upper incisors from the seventh to the tenth month. These teeth enable the child to _bite_, but not, be it observed, to _masticate_, for which function the molars are necessary. Now the first molars do not appear till the twelfth or fourteenth month; the second molars not till between the fourteenth and the twentieth month; and it seems to me certain that our primitive ancestors could not have obtained starch in any quantity until they reached this age; at the best, pre-cooking man was but scantily supplied with starch, and such slender supply as he had could only be rendered accessible to the digestive juices by vigorous mastication, which broke up the indigestible cellulose framework in which all vegetable starch is contained; hence, until the young human cut his molars, he had little opportunity of securing any starch. These considerations strongly suggest the desirability of giving but small quantities of starch before the twelfth month, and though the facts, that ptyaline appears in the saliva about the time the first incisors are cut, and that pancreatic juice develops its amylolytic ferment at the same time, show that the digestive organs are ready for the reception of some starch at the seventh or eighth month, yet I believe the quantity should be strictly limited. I am ready to admit that the modern child may have, indeed probably has, a greater power of digesting starch than his remote pre-agricultural ancestor; but even so, I am convinced that we should be on our guard not to over-gorge infants with this substance. Only a small quantity should be given before the twelfth month, and it should be gradually increased up to the twentieth month.

I have said that the pre-agricultural infant was unable to secure starch in any quantity by means of his incisors. These teeth enabled him, however, to obtain some soluble nutriment from fruits, and Dr. Sim Wallace has suggested that the early eruption of the lower incisors is for the purpose of enabling the infant to pierce the outer covering of fruits so as to permit him to extract the soluble contents by suction; and, accordingly, when these teeth are cut we may allow the child to bite at such vegetable substances as apples, oranges, and sugar-cane. The latter is a useful article of diet for children, for it provides soluble saccharide in a diluted form, and it is advisable that the child should receive his cane sugar well diluted, for it must be remembered that before the agricultural period man's supply of pure sugar was limited to wild honey which, consisting as it does almost entirely of mono-saccharide (grape sugar and fruit sugar), is very easily disposed of by the digestive organs. Nowadays, the less digestible cane sugar (which is a di-saccharide) is very largely consumed in the undiluted state, in which it is apt to set up disturbance. When, however, it is obtained by chewing the sugar-cane, it is diluted both by the water in the cane and by the saliva, and I should like to see children obtain most of their cane sugar in this way.

The consideration of the conditions obtaining for pre-agricultural man not only strongly suggests that the young human of to-day should be given starch in very moderate quantities up to the twelfth month, but it points an even more important lesson--viz., that this substance should be given not, as is the custom, as liquid or pap, but in a form compelling vigorous mastication, for it is certain that early man, from the time he emerged from the ape till he discovered how to cook his vegetable food, obtained practically all his starch in such a form; it cannot too often be repeated that uncooked starch in the natural state, locked up as it is in chambers of indigestible cellulose, has no nutritive value; these chambers need first to be broken up by prolonged and energetic chewing, and in this way much or most of the starch is converted in the mouth into dextrines and maltose, very little passing into the stomach in the crude state to set up disturbance in that organ and later in the bowel. If it is given as liquid or pap it will pass down as starch into the stomach, while if it is administered in a form which obliges the child to chew it properly, not only will the jaws, the teeth, and the gums obtain the exercise which they crave, and without which they cannot develop normally, but the starch will be so thoroughly insalivated that much of it will be converted within the mouth into maltose. How foolish to upset the child's digestive system by deluging it with liquid starch, and then to endeavour to correct matters by giving the malt extract which the child can and should himself manufacture within the laboratory of his buccal cavity.

Clearly, then, the child should make his first acquaintance with starch, not in the form of a liquid or pappy patent food, but in a solid and somewhat tough form. The best means of achieving this end is occupying my attention, and I hope soon to publish the results of my investigation. Meanwhile, I would point out that hard, well-baked crusts constitute a convenient form in which to administer starch to children. A piece of crust may be put in the oven and re-baked; this not only hardens it but helps to convert the starch into dextrine, which is a stage on the road to maltose. If the crust be then cut into a suitable shape and spread with bacon fat or fresh butter, it constitutes a most agreeable morsel. Later, we may give hard plain biscuits. The same principle should be acted upon during later childhood and youth: we should always give, as far as possible, the starch in a form compelling abundant mastication. Loaves should be shaped so as to give a maximum of crust and a minimum of crumb, and should be baked hard. Such loaves are quite as nutritious as the ordinary ones, and much more digestible, containing as they do an abundance of dextrine and not a little maltose, and compelling efficient mastication, especially if eaten, as they should be, without any fluid. A lady who has the catering

for a large number of girls gives the bread in this way, and she tells me that there is keen competition for the most crusty portions.

I do not say that starch in the liquid and pappy form should find no place whatever in man's dietary at the present day, for this would imply the prohibition of porridge, boiled potatoes, milk puddings, and the like. We cannot put back the hand of time and return to the food of our primitive ancestors, nor is it desirable that we should; but we can, at least, arrange matters so that a large proportion of the starch we consume shall be in a form inviting mastication, such as crusts, stale bread, stale cake, biscuits, and so forth. The less children eat of pastry, or, indeed, of any luxurious foods, the better; if brought up on a healthy dietary and under healthy conditions generally, they will relish their simple fare more than the choicest dishes of the epicure. I do not, I say, object to the child consuming a certain proportion of starch in the liquid or pultaceous form, for if, by bringing him up on a rational dietary, his instinct to masticate be afforded due opportunity to develop he will be likely to subject even soft vegetable food to something like adequate mastication; this will tend to mitigate the evils associated with such food, not only by facilitating the digestion of starch, but by flushing the mouth and promoting the health of the teeth and buccal mucous membrane.

The question how far children should be allowed to crack nuts may here be considered. If the child has been brought up on pappy food, and has in consequence brittle and ill-developed teeth, the cracking of hard nuts will be likely to injure them, and this is _a fortiori_ true if any of the teeth are carious or "filled." And not only nuts but hard food of any kind, such as ship's biscuits, may in these circumstances injure the teeth, as many of those who went through the recent South African campaign can testify. But if, on the other hand, the child has from the beginning been fed on coarse, hard foods, so that the teeth have been allowed to grow dense and strong, no harm is likely to ensue from cracking such nuts as filberts and Spanish nuts. If a squirrel or a monkey weighing a few pounds can do so with impunity, surely the young human should be able to also. The cracking should, however, be done by the molars, while such hard nuts as Brazils had best not be tackled at all.

Animal food does not need the same amount of mastication as vegetable food, since it is not digested in the mouth, though some contend that the mixture of proteid with alkaline saliva facilitates its subsequent peptonisation. Cooked animal food is, however, all the better for some mastication, owing to the coagulation of the proteids, and, in order to insure the efficient mastication of meat, fish, and poultry, Dr. Sim Wallace recommends that they should be given in large pieces cut thin. "Flat pieces about one inch square generally _necessitate_ a certain amount of mastication. It is difficult to swallow large flat pieces of meat without mastication, but when finely minced little or no mastication is called forth." The younger the child the more underdone should the meat be.

EXAMINATION OF THE MOUTH AND ADJACENT PARTS

If a child be brought up on the lines indicated and under healthy conditions generally, it is tolerably certain that the maxillary apparatus will develop normally, that the teeth will be strong and well opposed, and show little tendency to disease; but, inasmuch as the methods advocated are but seldom put into practice, disorders of the teeth, more especially caries and irregularities, are common, and hence with a view to promote more efficient mastication it is always advisable to examine our patient's teeth.

Each individual tooth should be inspected in a good light for the presence of caries, and careful note should be taken of the "bite," a normal bite implying not only a proper opposition of the two rows of teeth but the capacity of the lower ones to move freely across the upper; mere vertical movement of the mandible does not constitute efficient mastication. In this connection it must not be forgotten that an unopposed molar is useless for purposes of mastication, and it is by no means rare to find in a mouth several sound unopposed molars which are for this reason absolutely functionless. Nay, more than this, it may happen that teeth, perfectly sound ones, too, far from helping, may actually interfere with mastication; thus, among the poor, we sometimes find all the teeth gone save the upper canines and the lower incisors, and the teeth and gums being alike unable to come into contact, nothing worthy of the name of mastication is possible; it would be far better to be without any teeth whatever, for the toothless gums would then be permitted to come into contact along their entire extent, under which condition they gradually harden and come to be quite efficient grinding agents.

Next the gums, the alveoli, and the roots of the teeth must be examined, especially for the presence of erosion, tartar, and pyorrhœa alveolaris, this latter condition being evidenced by the welling-up of pus upon pressing the gums against the sides of the teeth.

If our examination of the mouth discloses anything likely to interfere with mastication the aid of the dentist should at once be sought, but every physician should be so far acquainted with disorders of the teeth as to be able to say, in the majority of cases, at all events, when this is necessary. I am convinced that far more illness than is generally supposed is attributable to dental defects,

and this even among the more leisured classes. With regard to pyorrhœa alveolaris, it has to be remembered that it not only does harm by causing loosening, lengthening, and shedding of the teeth, and thus interfering with mastication, but also by contaminating the stomach and the blood and thus upsetting the digestion and causing constitutional diseases, such as anæmia and arthritis; and inasmuch as poisonous discharges from the nose, the naso-pharynx, the pharynx, and the tonsils may act in a similar way, these parts also should be inspected in connection with the examination of the teeth. In the dust-laden atmosphere of towns they are very liable to disease, and even when healthy are necessarily dirtied; some go so far as to advise all town dwellers daily to wash out the nasal passages and to gargle the throat; but, whatever may be thought of this, it is certain that under existing dietetic conditions special means are needed in order to keep the mouth and teeth clean. When man fed on raw food this was not necessary, the food itself and the copious flow of saliva, induced by prolonged mastication, effectually cleansing these parts; but, under present conditions, food tends to remain within the mouth, especially between the teeth and in their crevices, and therefore special means are needed to remove it. This is done by “cleaning the teeth” and by rinsing the mouth.

The tooth-brush.--Probably the ideal method of cleaning the teeth is that adopted by many primitive and not a few semi-civilised peoples--viz., rubbing them with a twig of wood which has been teased out at one end so as to form a sort of brush by means of which the teeth can be burnished and food dislodged from them. The modern tooth-brush requires to be used with great caution, as it is capable of doing much harm, not only by removing the mucoid film, which, according to Dr. Wallace, protects the teeth from corroding agencies,[28] but probably also by injuring the edge of the gum and the neck of the teeth, and thus setting up the condition known as “erosion.” Certain it is that some of the best sets of teeth I have encountered have been wholly unacquainted with the tooth-brush. In any case the brush should be employed with great care; it should be soft, and should always be drawn away from the gums both on the inner and outer aspect of the teeth towards the biting surface, as well as across the latter, never transversely across the outer surfaces, as so frequently is done. The object of these procedures is to dislodge any particles of food that may have collected between the teeth or in their crevices. For this purpose the toothpick may also be employed judiciously. In order to render the enamel of the teeth white it is better to rub each tooth carefully with some soft material, such as chamois leather, rather than to scrub them with a brush. Tooth-powders should not be used as a matter of routine, but only occasionally and for appearance rather than for cleanliness, and should consist of some simple non-irritant material. Antiseptic powders and washes are to be scrupulously avoided, for it is neither desirable nor possible to render the buccal cavity aseptic; myriads of bacteria flourish within it, many of which play a useful part as scavengers. The time of all others for cleaning the teeth is just before going to bed, so that the food shall not be allowed to decompose in the mouth during the night. There will then be no need to use the tooth-brush in the morning.

Rinsing the mouth.--The mouth should be rinsed out as a matter of routine after each meal and on rising, and care should be taken to do this before the early cup of tea, so as not to contaminate the stomach with the buccal secretions which have accumulated during the night. Inasmuch as raw vegetable food has a cleansing effect on the teeth, it is often a wise plan, especially in the case of children, to finish a meal with some kind of fruit, such as an apple or an orange. It hardly seems necessary to insist upon the necessity for keeping all artificial dentures thoroughly clean.

PROFESSOR PAWLOW’S DEMONSTRATIONS OF PSYCHIC INFLUENCE IN DIGESTION

[In presenting a theory of human alimentation involving mental or nervous as well as mechanical and chemical factors which influence it for good, it is not often that an author is able to enlist the assistance of a complete battery of scientific confirmation to fortify his own crude observations taken direct from personal experience in the study of natural requirements.

Professor Pawlow, with his marvellously skilful investigation of the workings of the digestive secretions, and Dr. Cannon of the Harvard Medical School, by aid of persistent and patient X-ray studies, explain how it is that earned appetite and thorough mouth-treatment of food are preliminary necessities of easy digestion, and that disturbance or shock of any sort during the process stop digestive proceedings and endanger health. They show also that when the mouth is used to do _all that it can do_ in the work of digestion all the rest is easily accomplished by the NATURAL AUTOMATIC PROCESSES within the body.

They both show that we have, each of us, a certain responsibility in the matter of right digestion and healthy nutrition, and that all this personal responsibility is located in the head, in the mind, and in the mouth, and that while the alimentation is proceeding it is a sacred duty to do our part _right_, according to the intelligence that these most valuable demonstrations teach.

Professor Pawlow has allowed publication of his lectures in Russian and German, and recently Professor W. H. Thompson of the Physiological Department of Trinity College, Dublin, has made an English translation which is issued by Charles Griffin & Company

of London and J. B. Lippincott of Philadelphia.

The author has to express special gratitude to Professor Pawlow, Professor Thompson, Messrs Griffin and Lippincott for permission to reprint herein some entire lectures and extracts that bear especially on the practical understanding of our subject.

Professor Pawlow is one of the Board of Scientific Assessors mentioned in the REPORT of a PLAN for an INTERNATIONAL INQUIRY into the subject of HUMAN NUTRITION.

In one of the lectures, not here reprinted, Professor Pawlow gives merited recognition of the early statements of the French physiologist Blondlot relative to psychic influence on the digestive secretions made some half century ago, but discredited by physiologists since that time, owing to insufficiency of evidence brought forward in support of the statements.

Professor Pawlow's acknowledgment is so gracefully rendered that it is here given as a model of scientific courtesy.

"I have depicted the work of the gastric glands as we have seen it in our experiments, and as it has developed under our hands. Is the picture a new one? In its details, yes; but not in its fundamental features. However singular it may appear, the sketch of this picture was more than fifty years ago outlined by physiology. May this constitute another reason for our science relinquishing its characteristic shyness of new things and for its conversion to our interpretation of the phenomena under consideration!

"The talented author of the _Traité Analytique de la Digestion_--Blondlot--spoke in plain words of the importance of taking food, and of the specific excitability of the gastric mucous membrane. The facts adduced in the working up of his theory were naturally insufficient, but we must not forget that the first experiments on dogs with artificial gastric fistulæ had only just been performed. It is truly incomprehensible that the researches of Blondlot and his views upon the secretion of gastric juice have experienced during the past fifty years no completion, no additions, but, on the contrary, have passed out of sight, thanks to the faulty experiments and erroneous representations of later authors. Only in the works of a few writers--and those mostly French--has Blondlot's theory survived. Of other investigators we must give mention to Heidenhain, who has enriched the physiology of absorption in general, but more especially, in connection with the secretory work of the stomach, has discovered many important facts and has given birth to many fruitful ideas. From him proceed the subdivision of the secretory process according to periods and exciting agencies, as well as the suggestion that it would be important to investigate the individual food-stuffs in relation to the work of the stomach. Heidenhain's results are contained in his well-known article on the secretion of the cardiac glands of the stomach, published in the year 1879 in PFLÜGER'S ARCHIVES. The work of Blondlot and the additions of Heidenhain comprise almost everything of importance which was accomplished by physiology in fifty years concerning the conditions and mechanism of the secretory work of the stomach during digestion. Full of moment, however, for our subject was the obvious error that mechanical stimulation constituted an effective excitant of the gastric glands, and this error was in its turn a result of faulty methods."—HORACE FLETCHER.]

LECTURE IV

GENERAL SCHEME OF AN INNERVATION MECHANISM--THE WORK OF THE NERVOUS APPARATUS OF THE SALIVARY GLANDS--APPETITE, THE FIRST AND MOST POTENT EXCITER OF THE GASTRIC SECRETION

Constituent parts of a complete innervation mechanism--The special duty of the peripheral terminations of afferent nerves--The specific qualities of nerve cells--Analogy between the innervation mechanism of the salivary glands and that of the deeper-lying glands of digestion--The exciting agencies of the nervous mechanism of the salivary glands; their particular properties--Differences between the exciting agencies of the different salivary glands--Discussion of the sham feeding experiment--Mechanical and chemical stimulation of the cavity of the mouth has no effect on the gastric glands--The experiment of Bidder and Schmidt relative to psychic excitation of the gastric secretion--Conditions for success in this experiment--The passionate longing for food--the appetite--alone brings on the secretory effect in the sham feeding experiment.

GENTLEMEN,--As you have learned in the last lecture, and also in part have seen by direct experiment, the nervous system can influence the work of our glands in the most diverse ways. The vagus nerve, already burdened with many duties, has, in addition, proved itself to be an undoubted exciter of the gastric glands and of the pancreas. But we must also assign to the sympathetic nerve a similar _rôle_. This is a matter which cannot be doubted, so far as the pancreas is concerned, and is highly probable as regards the stomach. We also saw good reason for believing that these two nerves contained two different classes of fibres, secretory and trophic, a condition which had already been proved to exist by Heidenhain for the nerves of the salivary glands. As a

hypothesis we might even have proceeded a step farther and have divided Heidenhain's trophic nerves into separate classes of secretory fibres. Lastly, we advanced important experimental evidence to show the existence of special inhibitory fibres to the glands, and these fibres also run in the vagus, the list of whose functions seems almost interminable.

We obtained these results by division and artificial excitation of the nerves which run to the glands. But when, how, and by what means these nerves are thrown into activity during the normal course of physiological events remains a question.

In order to avoid repetition, and at the same time impart the utmost clearness to our representation, it may be useful to bring before your minds at once the plan of innervation of a given organ, all the more since this scheme is seldom completely followed out or adequately described in physiological text-books. Consequently, it is not borne in mind with sufficient precision by the majority of medical men.

A complete innervation mechanism consists of the peripheral endings of the centripetal (afferent) nerves, the centripetal nerves themselves, the nerve cells (a group of nerve cells connected with each other is termed a "nerve centre"), the centrifugal (efferent) nerves, and, lastly, their peripheral terminations. Physiology now accepts it as a settled fact, that nerve fibres serve only as _conductors_ of nervous impulses, which come in from contiguous links of the nervous chain. Only the peripheral endings of nerves and the nerve cells themselves have the power of transforming the external stimulus[29] into a nervous impulse. In other words, in the intact organism these alone constitute the normal receiving apparatus of the nervous system. Whether the peripheral ends of centrifugal (efferent) nerves are likewise able to function as normal sites for the application of external stimuli has still to be answered. Consequently, when any external agency excites the peripheral terminations--the receiving stations--of centripetal nerves in this or that organ, the effect of the stimulus will be conveyed through the centripetal nerves, as through a receiving wire, to the central station--the nerve cells. Here it becomes changed into a definite impulse and now comes back along the centrifugal nerves--the outgoing wires.

The utmost importance is to be attached to the fact that only the peripheral endings of centripetal (afferent) nerves, in contrast to nerve fibres themselves, respond to _specific_ stimuli; that is to say, are able to transform definite kinds of external stimuli into nervous impulses. The function of the end organs with which they are connected is therefore of a purposive nature; in other words, these organs are only called into play by certain definite conditions, and impart the idea of being aware of their purpose, of being conscious of their duty. We have long known that the peripheral endings of sensory nerves are possessed of a high degree of speciality, and cannot therefore have any doubt regarding the specific nature of the end organs of other centripetal nerves. This is a sore point in present-day physiology. But, notwithstanding our knowledge of the separate parts of the animal body, we shall only be able to form a true conception of the motive agencies of the whole complicated machine, when we have established the specific excitability of the end apparatus of every centripetal nerve, and have discovered all the mechanical, chemical, and other factors which throw this or that end apparatus into an active condition. I always look upon it as a period of scientific inadequacy so long as the effects of the most diverse external agencies upon any normal physiological process are admitted to be indistinguishable. As the work of the digestive canal is now represented in the majority of text-books, and consequently presented to the mind of the physician, it bears the impress of this period. To impart to the physician a more correct conception of this matter was my chief object in giving these lectures. I hope, indeed, to furnish you with evidence sufficiently convincing, that the alimentary canal is endowed not with mere general excitability; that is to say, does not respond to every conceivable form of agency, but only to special conditions which are different for the different portions of its length. Just as men and animals in the world are only able to maintain their existence and constantly adapt themselves to changing circumstances by aid of the peripheral endings of their sensory nerves, so every organ, indeed every cell of every organ, can only maintain its place in the animal microcosm, and adapt itself to the activity of innumerable associates, as well as to the general life of the whole, by virtue of the fact that the peripheral end apparatus of its centripetal nerves possesses a specific excitability.

The same applies to the nerve cells: obviously they are endowed with specific sensibility. Irrespective of the excitations which are communicated to them from centripetal nerves, they respond, as originators of nervous impulses, only or at least mainly to definite forms of mechanical, chemical, or other stimuli arising in the organism. This follows not alone from a number of physiological facts but also from various pharmacological data. Thus we learn that various drugs excite or annul the activity of definite portions of the nervous system, at least in the earlier phases of their effects. This specific excitability of nerve cells, just as much as the same property of peripheral end organs, lies at the bottom of the purposive action of these organs.

Hence, our next duty is to endeavour to discover the normal exciting conditions of the centripetal nerves belonging to the glands which we had under consideration in our last lecture, or, more correctly, to find out the conditions which excite the centres, as well

as the peripheral endings of the different nerves, which form parts of the nervous apparatus of these glands. We have, therefore, for each phase of the work of secretion, to find out that portion of the nervous mechanism which is for the time being under excitation, and to discover the primary agency by which this condition is elicited. This would include an exact analysis of the stimulating influence which mastication and food exert upon the nervous mechanism of these glands. We shall also be able more fully to comprehend the inner mechanism underlying the facts which formed the subject of the second lecture. This, of course, is an ideal programme which we can only follow out as far as the present state of physiology permits. It may now be instructive, and, for our further conclusions, advantageous, to glance shortly at the nervous control of the salivary glands.

The salivary glands, whose innervation has long ago been investigated, have generally been accepted as types of the deeper-lying digestive glands, and when it became necessary to form a conception of the mode of activity of the latter, medical science resorted to a bold analogy and thought of the nervous apparatus of the salivary glands. But the attempts of investigators to apply rigidly to others the scheme of innervation which holds good for the salivary glands, have done considerable harm to the usefulness of the analogy and have prevented our arriving at a correct idea of the plan of innervation of the abdominal glands. We have already had an example of this nature before us. In the salivary glands we have no clearly marked indications of nervous inhibition, and this circumstance has decidedly retarded the due development of our knowledge of the nervous control of the abdominal glands. Authors naturally expected to see a simple and prompt stimulation-effect from the same conditions of experiment which sufficed for the salivary glands, and the failure of this gave them, as they thought, the right to deny the existence of any extrinsic nervous influence upon the abdominal glands. The error is now obvious; the abdominal glands behave in some ways different from the salivary glands, and for their successful investigation, other conditions of experiment are necessary than those which held good for the former. In the working of the abdominal glands nervous inhibitory processes play a large part, but they are almost wholly absent in the case of the salivary glands. This is an additional warning that one must never push the conclusions drawn from analogy too far, but must constantly bear in mind that the life-functions of all organs are extremely complicated, and that the work of even the most apparently similar organs should be submitted to separate and careful observation. To me it appears that the unjustified analogy drawn between the abdominal and salivary glands has to be credited with another important misapprehension. And precisely for this reason I think it desirable to bring under consideration, if only in brief fashion, the conditions of work of the salivary glands, especially since Dr. Glinski has instituted in the laboratory some easily performed experiments which bear upon the matter.

The experiences of daily life teach us from the outset, that the activity of the salivary glands begins even before the introduction of food into the mouth. With an empty stomach, the sight of food or even the thought of it is sufficient to set the salivary glands at once into activity; indeed, the well-known expression, “to make one’s mouth water,” is based upon this fact. Hence a psychic event, the eager longing for food, must be accepted as an undoubted excitant of the nervous centre for the salivary glands. On the other hand, the same every-day experience, as well as numerous experiments upon animals, teach us that a number of substances, when brought into contact with the mucous membrane of the mouth, are likewise able to call forth a secretion of saliva. One even acquires the impression that everything brought into the mouth may reflexly influence these glands, the only difference being a gradual shading off in the effect, dependent upon the strength of the stimulation which the substance introduced is able to exert, and it appears to me that it is precisely this impression which has driven the idea into the background, that the peripheral end apparatus of the centripetal nerves of the digestive canal are specifically excitable. The facts were here correctly observed, but their indications erroneously interpreted.

The great multiplicity of excitants of salivary secretion, has without doubt, some connection with the complicated physiological functions of the saliva. This is the first fluid encountered by everything which enters the alimentary canal. It must, therefore, in a sense play the part of host to every substance taken in--moisten the dry, dissolve the soluble, envelop the hard and bulky with mucus in order to facilitate its passage down the narrow œsophagus; and submit certain forms of food material, such as starch, to a process of chemical elaboration. Nor is its duty by any means ended here. The saliva is secreted in the first compartment of the alimentary canal, which is at the same time the sorting-room of the organism. Much of what enters the mouth may prove in the testing process to be useless, or even noxious, and must either have its deleterious properties neutralised or be completely rejected. The saliva is secreted in the first instance to obviate injurious effects in some way; thus, for example, a strong acid is to a certain degree neutralised, while other corroding substances may be simply diluted, and by mere reduction of concentration have their harmfulness diminished.

In the second place, when the injurious substances have to be wholly removed, the saliva plays the _rôle_ of a washing-out fluid; otherwise the material, by clinging to the mucous membrane of the mouth, might in longer or shorter time gain entry into the blood and there develop its noxious influence. This last function of the fluid is hardly taken into account at all in physiology, and yet it is

evident that the saliva, as a cleansing fluid, must have a wide importance. If you only think of how often we are impelled to expectorate, that is, to wash out the mouth with saliva after something unpleasant, this will be clear. Such a view finds additional support when we reflect that a feeling of disgust produces almost as strong a flow of saliva as the sight of a tasty meal. In both cases the secretion performs the office of forerunner: in the first it prepares for the washing out of the mouth, in the second for the requisite elaboration of the food. Think how often, when something disagreeable enters the mouth, with what rapidity the saliva is poured out, even after the unpleasant substance has been for a considerable time removed, and not a trace more is apparent to the sense of taste. Indeed, long afterwards one has only to recall the circumstances to mind in order to bring on anew the secretion of saliva. Apparently the psychic excitation of the nerves of salivary secretion also ushers in the act of vomiting, which, as is well known, can be called forth by mental influence. Further, the function of the saliva just mentioned is probably the true physiological explanation of the feeling of disgust which many persons experience at the sight of the secretion itself.

Hence I hold that substances which obtain entry to the mouth set up a secretion of saliva only because we have here the seat of a definite physiological sense, and not because the peripheral terminations of the buccal nerves are devoid of specific excitability, and capable of being thrown into action by every desired form of stimulus. In other words, the specific excitability of the peripheral endings of the salivary nerves is very comprehensive and widely extended. This is no picture of the imagination, for it can be supported by facts. To say nothing of the testimony of earlier authors, that the salivary glands have each particular exciting agencies to which they specially respond, we can demonstrate the following facts from the material collected in our laboratory.

Dr. Glinski isolated the orifices of the salivary glands in dogs with portions of the adjoining mucous membrane, brought them out of the oral cavity, and caused them to heal into the edges of the skin wounds. In his first animal the ducts of the submaxillary gland were thus led outwards. By means of a Mendeljeff's clip, the wide end of a conical funnel of waterproof material was attached to the skin surrounding the orifice. To the narrow end a small test-tube, which served to collect the saliva, was attached by a wire. I now offer such an animal a piece of flesh, and, as you see, the tube fills up at once with saliva. I stop tempting the dog, hang on a new test-tube, and give it a few pieces of flesh to eat; once more a strong secretion of saliva results. A new tube is now attached to the funnel, the dog's mouth is opened, and a pinch of fine sand thrown in; again there is a flow of saliva. Once more a new test-tube; and now I apply to the buccal mucous membrane, the plume of a feather dipped in acid solution, with the result that I obtain a strong flow of saliva. One may employ a number of substances in this way, when a similar effect is always produced. You see, in this, such a comprehensive excitability of the innervation apparatus of the salivary glands that you might readily interpret it as meaning the power of response to all and sundry forms of stimulation. We now proceed, however, to another dog, whose parotid duct has in a similar manner been diverted outwards. The saliva is collected in the same way. We tempt the dog with a piece of flesh, but to our astonishment no saliva flows, and yet the animal is most eager for the savoury meal offered. Now we give it some raw flesh to eat; again the secretion of saliva is as good as absent; only when I come near can I detect one or two drops of saliva running down the sides of the tube. Probably you will say there is something wrong, either with the method or with the glands of the animal. But wait a little. I now give the dog finely powdered dry flesh, and obtain at once an abundant secretion. Should any one happen to think that the variation in the result is dependent, not on a different specific activity of the glands, but on individual differences in the dogs, I respond that Dr. Glinski has had an animal with double parotid and submaxillary fistulæ, and was able to observe on one and the same dog, a like behaviour on the part of the glands to that which we have just seen in two different individuals. An analogous experiment with bread was also carried out by Dr. Glinski. The eating of fresh moist bread produced no secretion worth mentioning, while dry bread, on the other hand, caused the saliva to flow in large quantities. The results of this experiment permit us to draw extremely instructive conclusions. In the first place, the several salivary glands are, as a matter of fact, very sharply differentiated in the conditions necessary for their activity--that is to say, in respect to the agencies which excite their nervous mechanisms. Secondly, the innervation apparatus of the parotid manifests a very sharp selective power in the choice, so to speak, of an adequate stimulus. The mechanical effect of large pieces of flesh is naturally much greater than that of the finely powdered material, and yet it was precisely to the latter that the glands responded. The stimulus is, therefore, not due to the mechanical, but to some other property of the food. This other property is obviously the dryness of the material. Our example illustrates how that which we may term "purposiveness" comes into play in the working of our glands and also how erroneous is the opinion that the mechanical stimulus is all potent. Indeed, previous authors have already pointed out that dry substances cause a specially free secretion of saliva, and yet physiological opinion throughout the length and breadth of the land, as expressed in text-books, has chosen to recognise a _universal_ instead of a _specific_ excitability. Dr. Wulfson, who is at present carrying on the investigation of salivary secretion in our laboratory, has added a very interesting observation to the results of Dr. Glinski already related. The parotid gland, which is hardly, if at all, excited when one offers fresh meat to the animal, responds with a very active secretion, when dry food (bread or powdered meat) is offered. This phenomenon is all the more surprising since the desire of the

animal for eating is much more strongly excited by flesh than by dry bread. I am quite convinced that an exact study of the exciting agencies of the three salivary glands will furnish a number of new data bearing upon the question in hand.

The second reagent which is poured out on the raw material in the digestive canal is the gastric juice. How, in the normal course of events, is the work of the gastric glands, which prepare this juice, called into play? With the first, and manifestly important factor, which has a relation thereto, you are already acquainted, and, indeed, have already seen. I refer to the production of gastric juice in the empty stomach, as a result merely of the swallowing of food in the so-called sham feeding of an œsophagotomised dog. When one takes into consideration the absolute independence of this factor, and the intensity of the effect, which makes itself evident in the secretion of a large quantity of juice of high digestive power, the exciting agency which brings about such secretion must be recognised as one of the most important and effective processes in gastric digestion. But in what does it consist? At first sight it appears--and when I previously drew your attention to the fact I expressed the opinion--that there is here a simple reflex effect from the cavity of the mouth upon the secretory nerves of the stomach, similar to the reflex excitation, _e.g._, of the parotid gland, by finely powdered flesh thrown into the mouth. Now, however, I assert quite emphatically that this is not the case. We have, it is true, in the activity of the salivary glands an analogous phenomenon to indicate--not, however, that of which we have just spoken. We might apply every conceivable form of stimulus which could possibly come into play in the act of eating, and yet would not obtain the slightest indication of secretory activity in the stomach. In this dog with a gastric fistula, and with also a divided œsophagus, I will try such an experiment, using the most effective chemical stimulus to the buccal mucous membrane, viz., acid solution.

The secretion of saliva begins at once, as you see; the acid is, therefore, effective. From the stomach, however, in spite of continued excitation, no secretion results, although the acid, mixed with the saliva, is swallowed and flows out again from the upper segment of the œsophagus--that is to say, passes along precisely the same path that the food takes in sham feeding.

We could experiment in the same way with a number of other substances: saline, bitters, pepper (strong local excitation), mustard, and so on, and always with the same results; a free secretion of saliva, but perfect quiescence of the gastric glands. We may even, with the same object, employ the soluble constituents of flesh in the form of a decoction, and likewise observe, in most cases at least, no sign of activity on the part of the gastric glands.

With the chemical we may also combine a mechanical stimulus. We can, for example, wipe out the mouth with a sponge soaked in the solution to be experimented with, but always with the same negative result. We may finally give such pieces of sponge, or even smooth stones of considerable size, to the dog to swallow, passing them back behind the anterior pillars of the fauces and allowing them to fall out again, from the upper portion of œsophagus. It may be added that a well-taught dog puts up with all these procedures without the slightest protest. You see that all the manipulations in this case are carried out with bare hands and without instrumental aid. One can easily train a dog to swallow stones which are placed in the anterior part of the buccal cavity. It simply makes a few chewing movements and swallows them down. The dog on which the acid experiment has just been made serves also for the swallowing of the stones. The attendant now places some pebbles in the front part of the mouth, when the animal rolls them round, as if chewing and gnawing them, and then swallows them. The stones fall out, as you see, from the œsophagus, and drop with an audible sound upon the table. This play with the stones has now lasted fifteen or twenty minutes (in the laboratory we have often kept it up for hours), and yet not a drop of gastric juice is to be seen.

In order to prove that the dog is perfectly healthy and normal, we lay aside the stones and proceed to our old experiment of sham feeding. As you see, the first drop of gastric juice makes its appearance precisely at the end of five minutes, and after a further five minutes we have collected more than 15 c.c. of the fluid; consequently there can be no doubt that in this dog both gastric glands and nerves are uninjured and function in normal manner. At one time we even had a dog which voluntarily took the stones out of one’s hand and swallowed them; the sagacious creature had seen our object in previous experiments and learned to perform it of its own accord! But in this case also the result was negative.

Clearly, therefore, neither chemical nor mechanical stimulation of the buccal mucous membrane is capable of reflexly exciting the nerves of the stomach. Further, it is obvious that the excitation of these nerves in sham feeding is not the result of a stimulation coincidently produced; that is to say, the excitement of the chewing and swallowing centres does not imply simultaneous action of the secretory centre of the gastric glands. In what, then, does this influence consist which is intrinsic to the sham feeding, but which we have not been able to reproduce in our analytical investigation? There is only one thing to think of, namely, the eager desire for food, and the feeling of satisfaction and contentment derived from its enjoyment.

It has, indeed, been known for forty years, thanks to the experiments of Bidder and Schmidt, that at times, the offering of food to a hungry dog, in other words, the excitement of a keen desire for it, is sufficient to cause a flow of gastric juice from the empty stomach. We shall presently have occasion to observe the force of this physiological factor. Here I bring before you another dog, likewise having a gastric fistula with divided œsophagus. The stomach has been washed out half an hour ago, and since then not a drop of gastric juice has escaped. We begin to get ready a meal of flesh and sausage before the animal as if we meant to feed it. We take the pieces of flesh from one place, chop them up, and lay them in another, passing them in front of the dog's nose, and so on. The animal, as you see, manifests the liveliest interest in our proceedings, stretches and distends itself, endeavours to get out of its cage and come to the food, chatters its teeth together, swallows saliva, and so on. Precisely five minutes after we began to tease the animal in this way the first drops of gastric juice appear in the fistula The secretion grows ever stronger and stronger, till it flows in a considerable stream. After the lapse of a few minutes we can count the number of cubic centimetres by tens. The meaning of this experiment is so clear as to require no explanation; the passionate longing for food, and this alone, has called forth under our eyes a most intense activity of the gastric glands. If the experiment be frequently repeated, one can easily observe that the keener and more eager the desire on the part of the dog for the food, the more certain and intense is the secretory effect. In extreme cases there is even a quantitative relationship between this effect and that of the sham feeding.

Here is an experiment of Professor Ssanozki, in which the secretory effect of the mere tempting of the animal with the sight of food is compared with that of sham feeding. A few threads of alkaline mucus had just escaped from the stomach, and then the excitation of the dog with flesh was begun. After six minutes the secretion commenced and continued as follows:

Duration of the flow. Quantity of the juice. 8 minutes 10 c.c. 4 ” 10 ” 4 ” 10 ” 10 ” 10 ” 10 ” 8 ” 10 ” 8 ” 10 ” 19 ” 10 ” 19 ” 3 ”

Then followed a sham feeding for six minutes.

Duration of the flow. Quantity of the juice. 17 minutes 10 c.c. 9 ” 10 ” 8 ” 10 ”

It is clear that in this case the tempting, instead of being less effective than the sham feeding, on the contrary excelled it.

Consequently, the observation of Bidder and Schmidt was perfectly correct. It cannot, however, be said that it received general recognition in physiology, or that it was sufficiently appreciated. There are authors who could never convince themselves of its reality, and in many physiological text-books it is not once mentioned. By way of explanation, we shall now consider how this matter must be dealt with by those who wish to observe the effect. It is only under certain conditions that it can be seen. Firstly, the animal must be healthy and vigorous; it must have a perfectly uninjured gastric mucous membrane; and this, from the description in the case of many authors who obtained a negative result, was not the case. Secondly, the success of the experiment, as stated above, is dependent upon the intensity of the desire for eating, and this, again, is dependent upon how freely and how long beforehand the dog had eaten, and also upon what it is tempted with, whether with a dish that excites its desire or leaves its interest unawakened. It is known that dogs have very different tastes, just as men have. Thirdly, one may find among the dogs positively careless, indifferent creatures, incapable of being perturbed in this way by anything which has not actually reached their mouths, and patiently waiting till the food is given them. Hence for success in the experiment, eager, impressionable, and excitable animals are necessary. Fourthly, one has to reckon with the sense and cunning of the dog, a factor which is not lightly to be disregarded. Often the animals perceive at once that they are only being teased with the food, become annoyed thereat, and turn away offended at what is being done before them. We must, therefore, so arrange matters as if the animals were not going to be disappointed but fed in reality. If attention be paid to these conditions the experiment of “psychic excitation of the gastric secretion,” as we usually term it, will be found to be as reliable as the experiment of sham feeding. When one is occupied for a length of time with the study of the gastric secretion under different conditions, one becomes convinced of what a dangerous source of error this psychic excitability may become in the different experiments. We must constantly fight, so to speak, against this factor, keep it ever in view, and guard against it. If the dog has not eaten for a long time, every movement,--the going out of the room, the appearance of the attendant who ordinarily feeds the animal--in word, every little triviality may give rise to excitation of the gastric glands. The minutest attention is necessary in order to avoid such sources of error, and we should not be far wrong if we said that much which has been ascribed in former investigations to the effect of this or that agency was in reality a result of unobserved psychic influence. Consequently, in order to verify our own conclusions concerning the effects of this or that condition, we have performed many of our experiments on sleeping animals, having beforehand convinced ourselves by frequent repetition that sleep exercises no restraining influence on the working of the gastric glands.

When we recall to mind the failure of our attempts to obtain a secretion of gastric juice by any stimulation whatever of the buccal mucous membrane, and at the same time see how constant and intense the action of this psychic impression is, we are forced to the inevitable conclusion that in our sham feeding experiment the whole secretory effect is due to the psychic stimulus, that is to say, to the keen desire on the part of the animal for food and the satisfaction of enjoying it.

In view of the importance of the act of eating, which even now is apparent, but which will become still more obvious when the succeeding periods of secretion are investigated, we have spared neither time nor trouble to arrive at a correct explanation of the mechanism of this factor. We have, therefore, taken in hand a number of modifications of the sham feeding experiment, and these investigations have confirmed the opinion at which we had arrived. If, for instance, the dog has been prepared by a long fast of two to three days, a very intense secretion of gastric juice will always be obtained by the sham feeding experiment, no matter what may be given it to eat, whether boiled or raw flesh, bread or coagulated egg-white, etc. The dog, however, which has not fasted, that is to say has been fed fifteen to twenty hours before, will pick and choose amongst the different foods, eating one with great greed, tolerating another, and refusing altogether a third, and, corresponding therewith, the amount and quality of the gastric juice will manifest wide variations. The more eagerly the dog eats the more juice will be secreted and the greater the digestive power which it possesses. The majority of dogs prefer flesh to bread, and correspondingly less juice will be produced by sham feeding with bread than with flesh. Sometimes, however, we find dogs which will devour bread with greater appetite than flesh. In these cases one obtains more and stronger juice in sham feeding with bread than with flesh. Here is a case in point: a dog is given boiled meat which has been cut into pieces of definite size, and the pieces follow each other at regular intervals of time. The animal eats, but soon, from its behaviour, you see that it develops no particular greed for the meal, and this observation is confirmed by the fact that after fifteen to twenty minutes it ceases taking the flesh. The secretion of juice has meanwhile either not begun at all, or only after a longer interval than five minutes, and remains scanty to the end. Now wait till the secretion has stopped and give the same dog raw flesh, either forthwith or next day, in pieces of the same size and at the same rate as before. The raw meat tastes excellently to the dog; it eats for hours at a time; the secretion of gastric juice begins precisely after five minutes and is very active. With another dog which prefers boiled to raw meat exactly the reverse occurs. Broth, soup, milk--towards which dogs are usually more indifferent than towards solid food--often produce in sham feeding either no secretion at all or only very little, although broth, for instance has essentially the same taste as flesh.

It is therefore clear that in sham feeding the psychic effect may readily become an absolute and independent factor. All the conditions which we enumerated above, and which are necessary for the successful production of the psychic effect, hold good in combined form for the sham feeding experiment. The dog eats with greed before one’s eyes; the food which it receives is pleasant; it not only imagines food but actually eats it, and has therefore no reason to feel offended, for naturally the idea does not occur to any of the dogs that all their trouble is in vain.

Consequently, in the sham feeding experiment, by the act of eating, the excitation of the nerves of the gastric glands depends upon a psychical factor which has here grown into a physiological one, that is to say, is just as much a matter of course, and appears quite as regularly under given conditions as any other physiological result. Regarded from the purely physiological side, the process may be said to be a complicated reflex act. Its complexity arises from this, that the ultimate object is attained by the joint working of many separate organic functions. The material to be digested--the food--is only found outside the organism in the surrounding world. It is acquired not alone by the exercise of muscular force, but also by the intervention of higher functions, such as judgment, will, desire. Hence the simultaneous excitation of the different sense organs, of sight, of hearing, of smell and taste, is the first and strongest impulse towards the activity of the gastric glands. This especially applies to the two latter senses, since they are only excited when the food has already entered the organism, or at least has arrived very near it. It is by the establishment of this passionate desire for eating that unerring and untiring nature has linked the seeking and finding of food with the commencement of the work of digestion. That this factor, which we have now carefully analysed, stands in closest connection with an every-day phenomenon of human life, namely, appetite, may easily be predicated. This agency, which is so important to life and so full of mystery to science, becomes here at length incorporated into flesh and blood, transformed from a subjective sensation into a concrete factor of the physiological laboratory.

We are therefore justified in saying that the appetite is the first and mightiest exciter of the secretory nerves of the stomach, a factor which embodies in itself a something capable of impelling the empty stomach of the dog in the sham feeding experiment to secrete large quantities of the strongest juice. A good appetite in eating is equivalent from the outset to a vigorous secretion of the strongest juice; where there is no appetite this juice is also absent. To restore appetite to a man means to secure him a large stock of gastric juice wherewith to begin the digestion of the meal.

LECTURE V

PERIOD OF OCCURRENCE AND IMPORTANCE OF THE PSYCHIC OR APPETITE JUICE IN THE SECRETORY WORK OF THE STOMACH--THE INEFFICIENCY OF MECHANICAL STIMULATION OF THE NERVOUS APPARATUS OF THE GASTRIC GLANDS

The psychic secretion is the normal commencement, in the majority of cases, of secretory activity on the part of the gastric glands. If the meal be subdivided and administered at intervals, the psychic juice appears each time--Demonstration of “appetite juice” in a dog with an isolated gastric _cul-de-sac_. The work of the gastric glands if appetite juice be avoided by introducing food through a gastric fistula unperceived by the animal--Digestion of flesh by the stomach with and without sham feeding--Duration of the secretory influence of sham feeding--After the cessation of the psychic effect, how is the secretory work of the stomach maintained?--Experiments to prove the ineffectiveness of mechanical stimulation: excitation of the mucous membrane by means of a glass rod, a feather, a puff of sand, and by rhythmic dilatation of an india-rubber ball--Contact between the food and the stomach-wall may indirectly call the activity of the glands into play by awakening or increasing the desire for food.

GENTLEMEN,--On the last occasion we made ourselves acquainted with the first normal impulse which, in the natural course of events, calls into activity the innervation apparatus of the gastric glands. This impulse is a mental one, and consists in a passionate longing for food, that which in every-day life, and in the practice of the physician, is called “appetite,” and which everybody, both medical and lay, endeavours carefully to promote. We may now venture to say explicitly, APPETITE IS JUICE, a fact which at once displays the pre-eminent importance of the sensation. Medical science endeavours to assist the debilitated stomach by introducing the active constituent of gastric juice--pepsin--from without, or by prescribing other remedies believed to promote its secretion. It is, however, of interest to follow our experimental investigation still farther. What position is to be assigned to the “psychic” or “appetite-juice”[30] in the course of normal gastric digestion? Is any definite _rôle_ to be attributed to it? What course does gastric digestion take when it is absent? Fortunately to all these important questions satisfactory answers are forthcoming by experiment. We have only to regret that these answers come so late.

Let us recall to memory how the secretion of gastric juice proceeded after feeding with flesh or bread in the case of our dog with the isolated miniature stomach. The following are the quantities and digestive capabilities of the first two hourly portions of juice after the administration of 200 grams of flesh or bread (experiments by Dr. Chigin):

■■■

interest it to the same degree as flesh or bread, you will find the initial increase in quantity and strength of juice does not appear. Offer the animal milk, for example, which in sham feeding, especially if it does not last long, calls forth, as a rule, no secretion, or at all events only very little, and the rapid flow of the commencement--the already-mentioned initial rise--absolutely fails to appear. You have already seen the figures which deal with this matter; I think it necessary, however, to bring them forward again in order that you may be better able to compare them with the secretion after flesh and bread.

The dog was given 600 c.c. of milk (experiment by Dr. Chigin).

Hour. Quantity of juice. Digestive power. 1st 4.2 c.c. 3.57 mm. 2nd 12.4 ” 2.63 ”

We have now begun the analytical examination of the variations of our secretory curve. But owing to the importance of the matter we did not confine ourselves to conclusions which might be drawn from earlier investigations. We turned to new forms of experiment for further proof.

Thus we divided the ordinary ration of flesh given to our dogs--400 grams--into four equal parts, which were administered at intervals of an hour and a half. (Experiments by Privat docent Kotljar and Dr. Lobassoff.) Each time after the dog received its 100 grams of flesh we were able to detect a rise both in the quantity and in the digestive power of the juice. The following table shows the figures in question:

■■■

This experiment proves to us, first, that the main and miniature stomachs work in perfectly parallel manner with each other. The beginning, the end, and the intermediate variations of the secretion correspond in both cases. Secondly, the digestive power of the secretion coincides in both, and is the same which was observed in the so-called sham feeding. It has here remained at the same height till the cessation of the secretion, without falling to the lower value which we observed from the beginning of the second hour onwards, after normal flesh feeding.

This was also confirmed later, when we performed an œsophagotomy on the dog, and carried out sham feeding in typical form. Here follows one of these experiments taken from Dr. Lobassoff's article.

The first drop of juice appeared from both cavities during the sixth minute after commencing the feeding, which was kept up for half an hour. The further course of the secretion was as follows:

■■■

into ■ (Lobassoff). ■ quan- ■ ■ ■ ■stomach(Lobassoff)■ ■ tity ■ ■Hour.■——————————■——————————■——————————■——————————■——————————■——————————-■ in two■ ■

The progress of juice secretion in the above is also represented in the following curves:

[Illustration: FIGURES 4-7.—A. Ordinary curve of gastric secretion (200 grms. flesh). B. Curve from direct introduction of food (150 grms. flesh). C. Sham feeding with same. D. Summation of B and C.]

As you see, the curve which represents the results of the direct introduction of flesh ascends much more slowly and does not attain anything like the height of that caused by normal feeding with the same food. But if the quantities obtained by direct introduction of the flesh be added to those of sham feeding, the resulting curve is almost identical with the normal.

In like manner the digestive power of the secretion in the foregoing experiments can be dealt with, and with the same result. It is a good instance of how a secretion curve can be synthetically constructed from its constituent factors.

Finally, I am able to demonstrate to you the following instructive experiment. In the presence of some of my listeners, whom I had invited to attend an hour before the lecture, I carried out the following procedures on two dogs, both of which had ordinary gastric fistulæ and were, besides, œsophagotomised. Into the stomach of one, while its attention was distracted by patting and speaking kindly to it in order to avoid arousing any thoughts of feeding, a definite number of pieces of flesh were introduced through the fistula. The morsels were threaded on a string, the free end of which was fastened to the fistular cannula by inserting a cork. The dog was then brought into a separate room and left to itself. A like number of pieces was introduced into the stomach of the other dog in the same way, but during the process a vigorous sham feeding was kept up, the animal being afterwards left alone. Each dog received 100 grams of flesh. Since then an hour and a half have elapsed, and now we may draw the pieces of flesh out by means of the thread and weigh them. The loss of weight, and consequently the amount of flesh digested, is very different in the two cases. In that of the dog without sham feeding the loss of weight amounts to merely 6 grams, while the flesh withdrawn from the stomach of the other dog weighs only 70 grams, that is to say, was reduced by 30 grams. This, therefore, represents the digestive value of the passage of food through the mouth, the value of an eager desire for food, the value of an appetite.

I give also a series of figures obtained by Dr. Lobassoff in analogous experiments. Into the dog’s stomach 25 pieces of flesh (100 grams) were brought. The flesh remained two hours in the cavity. Without sham feeding 6.5 per cent, with eight minutes' sham feeding 31.6 per cent, of the quantity was digested.

Again: the flesh remained an hour and a half in the stomach; without sham feeding 5.6 per cent, with five minutes' sham feeding 15 per cent, was digested.

Once more: the flesh remained five hours in the stomach; without sham feeding 58 per cent, with sham feeding 85 per cent, was digested, the balance of undigested food being 42 per cent in the one case and 15 per cent in the other.

I must, however, add that from the nature of this experiment it is not well adapted for class demonstration, and may often fail. On the one hand, it is not at all easy to conceal the introduction of the flesh from the dog; on the other, the unusual and distracting surroundings of the animal often causes a short period of sham feeding to have less effect than would otherwise pertain. In order to avoid such failures it is better before an audience to carry out this experiment only on dogs accustomed to appear in the lecture theatre, and of whose temperament the experimenter is well assured.

I hope you have now been convinced of the great importance which is to be attached to the passage of food through the mouth and œsophagus, or, in other words--and this, according to our former experiences, means the same thing--to the eager desire for food. Without this longing, without the assistance of appetite, many forms of food-stuffs which gain entry to the stomach remain wholly devoid of gastric juice. Others, it is true, excite a secretion, but the juice poured out is scanty and weak.

It is only later, when we have still more fully recognised the conditions upon which the secretory work of the gastric glands depends, that we shall be able to grasp the meaning of these facts in a more comprehensive manner. For instance, why does bread brought unnoticed into the stomach of the dog cause no secretion for hours, while flesh tolerably soon (after twenty to forty minutes) provokes this act? This will be explained in the next lecture; now, however, we must consider other questions.

How long does the after-effect, the echo of the first impulse to the secretory nerves of the stomach, continue to last? How long does appetite juice continue to flow after the normal act of eating, which, especially in the case of animals, is not of long duration? We have already determined many times, not only on our dog with the isolated stomach, but also on other animals, how long the after-effect of sham feeding is continued.

Here, for example, is an experiment from the article of Professor Ssanozki which deals with the point. The dog had a gastric fistula and also an opening leading into the œsophagus. After a sham feeding of five minutes the secretion began, and was continued as follows:

Time in minutes. Quantity. Digestive power. 10 25.5 c.c. 8.1 mm. 10 20.0 ” 8.0 ” 10 13.5 ” 6.8 ” 10 11.0 ” 7.5 ” 10 8.5 ” 8.1 ” 10 6.5 ” 9.0 ” 20 13.5 ” 7.4 ” 20 11.0 ” 7.2 ” 20 7.0 ” 7.2 ” 20 11.5 ” 6.8 ” 20 11.0 ” 6.5 ” 30 6.5 ” 7.6 ” 20 5.5 ” 7.2 ”

The effect, therefore, even after a short period of sham feeding, stretches over a length of time. Naturally the same holds good for the taking of food in the normal way. One must, however, bear in mind that in sham feeding, with all the force and reality of a hunger sensation not satisfied, the eager desire for food, the effective agency, becomes more and more accentuated, and therefore the secretory influence is prolonged and more powerful. In normal feeding, however, the quelling of the longing, the feeling of satisfaction which, as is well known, sets in long before the termination of the digestive period from the mere filling and distension of the stomach, must diminish the desire for food, and, consequently, bring the secretory effect to an end.

It is, therefore, improbable that the whole secretory process in the stomach, which, in the case of certain kinds and quantities of food, lasts from ten to twelve hours, is dependent on the factors which we have up to the present investigated. This is all the more obvious since a sham feeding of five minutes, even under the most favourable circumstances, does not call forth a secretion for longer than three to four hours. We must, therefore, seek for other exciting agencies of the innervation apparatus of the gastric glands.

Why and wherefore is the secretion instituted by psychic influence maintained? What would first occur to all your minds is naturally the immediate influence which the food exerts upon the walls of the stomach. And this is true, but it does not happen in the simple, direct fashion current in the minds of many physiologists and physicians. When I said that bread or boiled white of egg, introduced directly into the stomach, may not for hours produce a trace of secretion, probably many of my hearers may have asked themselves with natural astonishment, “How, then, is the effect of the forced feeding of phthisical and insane patients, and the artificial feeding of those with gastric fistulæ (performed on account of stricture of the œsophagus) to be explained?” I will introduce my answer by a very unexpected pronouncement relative to the assertion that mechanical stimulation of the stomach wall by food constitutes a reliable and effective means of calling forth the secretory work of the glands. This assertion, which is so categorically set forth in many text-books of physiology, and which consequently has gained hold of the mind of the physician, is nothing else than a sad misconception degenerated into a stubborn prejudice. My own statement, repeated in many published articles, and at the meetings of various medical societies, that this dictum is only a picture of the imagination, has met, for the most part, either with an unbelieving shake of the head or else with a direct avowal that “it cannot be so.” I regret exceedingly that these steadfast unbelievers are not here, so that we might together bring the matter before the tribunal of fact, to the demonstration of which we will now proceed. To this matter I attribute very great importance. It is on this ground, according to my opinion, that the whole battle must be fought out between the generally accepted view that every agency is capable of exciting the gastric mucous membrane and the theory that it is only excitable by specific and selected stimuli. If once the defenders of the old opinion are driven from their position and obliged to admit the inefficiency of mechanical stimulation, there would be nothing further left for them than to build up new theories and search out old facts concerning gland work which have hitherto been rigidly kept in the shade. We may take it that it is mainly because people were so seized with the belief in the direct and simple mechanical explanation that Bidder and Schmidt’s experiment of the excitation of gastric secretion by mental effect has been so little taken into consideration, notwithstanding that it appeared so thoroughly reliable and convincing.

I will now repeat the experiment of mechanical stimulation of the gastric mucous membrane before you in the well-known, traditional, and classic manner. Here is a dog with a gastric fistula on which a cervical œsophagotomy has in addition been

performed. I open the fistula; as you see, nothing flows out of the stomach; it was washed out clean with water an hour ago. We take the celebrated feather and also a tolerably strong glass rod. Folds of blotting-paper saturated with red and blue tincture of litmus are placed at hand. I now ask my assistant to continuously move the feather and glass rod, alternately, in all possible directions in the stomach, changing from one to the other every five minutes. On removal from the stomach each is carefully dried with red and blue blotting-paper. You have all seen, gentlemen, that this procedure has now been kept up for half an hour. From the fistular orifice not even a single drop has escaped, and, moreover, the drops of moisture on all the pieces of red blotting-paper I have been able to hand to you have assumed a distinct blue tinge, caused by the moisture of the alkaline mucous membrane. The blue pieces, however, have merely been made wet without altering their colour. Consequently, with the most thorough mechanical stimulation of the whole cavity of the stomach, we have not been able to find a single spot possessing a noticeable acid reaction. Where, then, are the streams of pure gastric juice of which we read in text-books! What objection can be raised against the conclusiveness of this experiment? In my opinion only one: that we are dealing with a dog out of health, whose gastric glands from some possible cause are unable to react normally. This single objection can be set aside before your eyes. After failing with the mechanical stimulation, we proceed forthwith to the sham feeding of the same animal. The dog takes the food offered it with keen appetite, and you see that, exactly five minutes after beginning the feeding, the first drops of juice appear from the stomach, followed by others faster and faster. I catch a couple of drops on the blue litmus paper, and you see that they produce bright red specks on the blue sheet. After thirty minutes' sham feeding we have collected 150 c.c. of juice, which, without filtering, looks as clear and transparent as water.

We cannot, therefore, possibly doubt that, when the proper stimulus is used, the gastric glands react to it in a perfectly normal fashion, furnishing a healthy gastric juice. From this it irrefutably follows that only one explanation is to be found for the negative result in the first half of our experiment, viz., that the mucous membrane of the stomach, so far as secretory activity goes, is perfectly indifferent to mechanical excitation. And yet this mechanical stimulus is demonstrated as an exciting agency in the physiological lecture theatre. I venture to think that this lecture experiment from now onwards will quit the field, and give place to the one I have just shown you. This apparently simple experiment of mechanical stimulation can, however, only be successfully performed when certain very obvious rules are followed. These, however, physiologists have not observed, probably on account of a preconceived belief in the effectiveness of the mechanical stimulus. These rules are two. First, it is necessary that the stomach should be clean, and that nothing shall gain entry to it from without. Such conditions were not formerly fulfilled. It is true the stomach was emptied by removing the stopper from the fistular cannula, but it was not washed out till an acid reaction was no longer given, and consequently preformed gastric juice was left behind between the folds of the mucous membrane. At the same time saliva from the cavity of the mouth could gain entry, which quickly became acidified in the incompletely emptied and imperfectly washed-out organ. It is, therefore, not surprising that the glass tube, by setting up contractions of the stomach, was the means of expressing small quantities of acid fluid from the fistula-tube. (The relationship between mechanical stimulation and the motor functions of the stomach is not to be confounded with what we are here speaking of.) That matters are as I state, and that the facts correspond to the explanation is proved by this; namely, that nobody till now has obtained genuinely pure gastric juice of an acidity amounting to 0.5 or 0.6 per cent. It is only necessary to call to mind that Heidenhain, when determining the acidity of the juice first obtained from the resected stomach, was placed in no little doubt as to whether his results (0.5 to 0.6) were correct, and his assistant at the time (Gscheidlen) was set to verify the correctness of his standard solutions. The acidity of the “purest” juice known at that time was scarcely 0.3 per cent. As a further proof that none of the older observers ever really obtained a secretion from mechanical stimulation pure and simple, we may adduce the fact that none of them made mention of the constant and precise period of five minutes' latency. To overlook this was not possible if a genuine excitation of the glands had been obtained.

Of no less importance is the second condition when we wish to perform the experiment of mechanical stimulation in the correct way. It is very necessary that the gastric glands be not already in activity at the beginning of the experiment, and also that during the experiment no impulse comes into play, which of itself, apart from mechanical excitation, could excite the glands to secretion. Nor have we any proof that observers formerly waited for hours before commencing the experiment and convinced themselves that the gastric glands had ceased working. On the contrary, we have not the slightest evidence to indicate that the authors had attempted to guard against accidental psychical stimulation of the glands--a matter which we have seen is of considerable difficulty. And some dogs are so easily excited in this way that it is almost impossible to bring their glands to rest, or at least it is necessary to wait for hours. The experimenter must strain his whole attention to preserve such an experiment free from objection. It is only necessary that some food be near the dog, or that the hands of the attendant who has prepared the food should smell of it, or that some other similar circumstance should come into play, and the glass tube, quite undeservedly, will be made answerable for the excitation of the gastric glands. As you have just seen, both of our conditions have been fulfilled on the dog before you, and the

result of the experiment stands in irreconcilable contradiction to those of the laboratory and lecture experiment of former times.

The importance of the experiment, which I have already dwelt upon, justifies me in making still further demands upon your attention in order to show you two modifications of it. Nobody has as yet said, with regard to mechanical stimulation, that in order to obtain results the mechanical agency must simultaneously come into contact with numerous points of the inner surface of the stomach. But in order to meet this possible objection I will now show you two new modifications. Again a similar dog is used, that is to say, one on which both gastrotomy and œsophagotomy have been performed. The stomach has been washed out clean and is at present in a state of complete rest. Into the fistula I bring a thick glass tube containing a number of small openings (2 to 3 mm. diameter) at its rounded end. The other end of the tube is connected with a glass ball containing tolerably coarse sand. Leading into the ball is a second tube, with which an india-rubber pump can be connected and a blast of sand blown through. By rhythmic compression of the india-rubber ball I inject sand with considerable force into the stomach, and this play is kept up for ten to fifteen minutes; nevertheless, we see no trace of gastric juice. The sand falls out again between the side of the cannula and the glass tube, and it is either dry or scarcely moistened, but in no case is it able to turn blue litmus red. And yet we are here dealing with a strong and widely diffused stimulus. Look for a moment at the performance of the bellows outside the stomach. From every opening of the tube--numbering considerably more than ten--a strong stream of sand is ejected. If you hold your hand against it, you feel quite distinctly that the grains of sand strike with considerable force. And now, when our experiment is ended, we may convince ourselves by sham feeding, in easy and unquestionable fashion, that the innervation of the dog's stomach is perfectly normal.

Yet another experiment on a similar dog. Into its empty and resting stomach an india-rubber ball is introduced. This is distended with air by means of a syringe till it is as large as a child's head and maintained in this condition for a time, afterwards being allowed to collapse. The procedure is kept up for ten to fifteen minutes. During this time not a single drop of juice has appeared from the stomach. The surface of the ball taken out of the organ is everywhere alkaline. And here also subsequent sham feeding shows that the dog is in a suitable condition for the experiment. I must add that in making this observation the dog must not be too hungry, that is to say, must have been fed within ten to twelve hours before, otherwise a psychic excitation of the secretion can readily be induced.

If one dispassionately regards this question, and if any of our methods for the study of gastric secretion are reliable, one must be convinced step by step in the laboratory of the uselessness of mechanical stimulation. In the case of dogs with an ordinary gastric fistula, and failing some special reason, not a drop of gastric juice ever escapes from the stomach other than during the digestive period. How could this be the case if the mechanical stimulus were effective, since the inner rim of the fistula-tube is continuously in contact with the gastric mucous membrane? The same holds good for the dog with resected stomach. During the experiment a glass or india-rubber tube is brought sufficiently far into the _cul-de-sac_ to catch the juice, and yet not a drop flows through the tube, nor does its inner surface ever become acid, so long as true secretory conditions are absent. Moreover, the tube has tolerably often to be taken out and set right.

In the ordinary gastric fistula in dogs, when the operation has lasted a long time--over a year--folds of mucous membrane are often formed in the neighbourhood of its inner orifice which completely close the tube. In these cases a long, thick, perforated metal tube has to be passed in deeply, and yet the manipulation of itself never calls forth a secretion. Further, it is a daily occurrence to find in the stomach of the dog thick rolls of hair, and yet their presence in no way hinders the arrest of the secretion, which occurs when digestion has ceased. Such an occurrence would have been specially obvious in our dog with the isolated stomach, since it was bedded with sawdust in order to guard against maceration of the wound by juice trickling out. Very often we found enormous quantities of sawdust in the stomach, as much as half a pound weight; obviously the dog had licked the wound from adherent sawdust, which it then swallowed, together with that sticking to its nose. And yet these particles of sawdust of themselves, which certainly acted as mechanical stimuli, never caused a secretion. It appears to me that this long series of facts ought to suffice to carry the supposition to its grave that by direct mechanical stimulation one is able to set the neuro-secretory apparatus of the stomach into activity.

And yet the feather and the glass tube continue the even tenor of their ways to this moment and function in some text-books, yea, even in articles which specially treat of gastric secretion as exciters of the gastric glands. There are, it is true, a few physiologists who hold mechanical stimulation, in relation to gastric secretion, not to be very effective, and give it a subordinate position in the series of exciting agencies, but as yet I know of no other physiologist who has wholly denied its influence, and who has not held it possible to obtain at least some juice by it.

To conclude this lecture, we will take into consideration a question connected with the matter we have just discussed. Since the contact of food with the gastric mucous membrane has no direct influence on the secretion, is its entry into the stomach devoid of all connection with the secretory process?

It can hardly be doubted that, under normal conditions, the stomach is the seat of certain definite sensations, that is to say, its surface has a certain degree of tactile sensibility. This sensation is, as a rule, very weak, and the majority of people become accustomed to pay no heed to it in the normal course of digestion. They obtain their sensations of general well-being, and especially of satisfaction from the enjoyment of food, without taking cognisance of the factors contributing to them. The feeling of general hunger, however, is referred solely to the stomach.

On the other hand, all of us have met with men who could describe exactly, and with gusto, how they were able to follow a special tit-bit, or a mouthful of a favourite wine, the whole way through the œsophagus down to the stomach, especially when the latter happened to be empty. Naturally the gourmand, who directs his attention continuously to the act of eating, can in the end distinctly perceive sensations, and even call them up to the consciousness, which in other people are normally masked by other sensations and impressions. We may therefore take it that the satisfaction derived from eating is caused not only by stimulation of the mouth and throat, but also by impulses awakened by the passage of the food along the deeper portions of the œsophagus and by its entry into the stomach. In other words, food which merely passes through the mouth and throat produces less enjoyment and excites, therefore, a less feeling of appetite than the food which passes the whole way into the stomach. The appetite, the eager craving after food, is, indeed, a very complex sensation, and often not merely the need of the organism for food material is necessary for its excitement, but also a condition of thorough well-being, together with a normal healthy feeling in all parts of the digestive tract. For this reason it is easy to understand how patients who have diseased sensations in these organs, and who have no feeling of appetite, no desire for food, remember the sensations, whether consciously or unconsciously, even when they are no longer present. Cases are known to neuro-pathologists where people with gastric anæsthesia suffered from this loss of appetite. Such patients are no longer conscious of having stomachs, and dislike the idea of eating because the food, as they express it, appears to fall into a strange empty sack. In this way one can also conceive how the appetite becomes lost in cases of long-continued obstruction of the alimentary tube. The patients forget their stomachs, and in such instances direct introduction of food into the organ, after an operation, may suddenly bring back the appetite.

As a further illustration, I may be permitted to give an instance from my own personal experience. After an illness with which a transient but high fever was associated, although otherwise fully recovered, I had lost all desire for food. There was something curious in this complete indifference towards eating. Perfectly well, I only differed from others in that I could with ease abstain from all food. Fearing that I should collapse, I resolved on the second or third day to endeavour to create an appetite by swallowing a mouthful of wine. I felt it quite distinctly pass along the œsophagus into the stomach, and literally at that moment perceived the onset of a strong appetite. This observation teaches that the tactile sensation of the stomach at the moment of entry of food is capable of awakening or increasing the appetite. It is known that withholding food from the organism, or in other words the creation of a necessity for food, does not lead immediately, nor in all cases, to the production of an appetite, to a passionate craving for food. How often does it happen that the ordinary hour for a meal has struck, and yet, owing to some keenly interesting occupation, not the least desire for food is felt? It is known to everybody, indeed it has become a proverb, that real appetite first sets in with eating. If this be true, the initial impulse towards awakening an appetite may originate in the stomach and not in the buccal cavity. When we spoke above of the desire for food being the excitant of the secretory nerves of the stomach, we naturally meant the passionate and conscious longing for food, that which is called “appetite,” and not the latent need of the organism for nourishment, the lack of nutrition, which has not yet been transformed into a concrete passionate desire. A good example which enables us to differentiate between these two factors is furnished by our dogs with sham feeding. The necessity for food exists in such cases even before the experiment; the juice, however, only begins to flow as soon as this need has taken the form of a passionate longing. It is therefore quite possible that in the case of some dogs, and at a certain stage of hunger, the touching of the gastric mucous membrane with any object at hand, its mechanical excitation, its distension by the food mass, may give the impulse which excites the appetite, and when the appetite is awakened the juice flows. This is possibly a third reason why, in the old experiment, the mechanical stimulus came to be considered effective. Viewed from this point it may, to a certain degree, lead to a reconciliation between my assertion concerning the inefficiency of the mechanical stimulus and the generally prevailing belief. I further also admit that mechanical excitation will at times call into play the work of the gastric glands, not however directly by means of a simple physiological reflex, but indirectly, after it has first awakened and enlivened the idea of food in the dog’s consciousness, and thereby called forth the passionate desire. I hope that the foregoing will in no way lead to a confusion of ideas in your minds, but will assist you to an exact and concrete analysis of the previous simple explanation of the facts. This representation, which bears more

or less of a hypothetical character, could, of course, be submitted to experimental proof. For such it is only necessary to compare the influence which sham feeding exercises in an œsophagotomised dog with that in one having a simple gastric fistula.

LECTURE VIII

PHYSIOLOGICAL ACTION AND THE TEACHING OF INSTINCT: EXPERIENCES OF THE PHYSICIAN

It would be desirable, in the interests of medicine, that the methods described in these lectures should be employed in experimental investigations into the pathology and therapeutics of the digestive canal on the lines laid down--The fact that the beginning of the secretory work in the stomach depends upon a psychic effect harmonises with the experiences of every-day life, namely, that food should be eaten with attention and relish--To restore the appetite has from all ages been the endeavour of the physician--The indifference of the present-day physician towards appetite--Probable causes of this--Curative remedies based upon a restoration of appetite--The therapeutic effects of bitters depend upon the excitation of appetite--The usages of the mid-day meal are in agreement with physiological requirements--Physiological reasons for certain instinctive customs and empirical regulations--Importance of an acid reaction of the food--Dietetics of fat and its therapeutic application--The peculiar position of milk among food-stuffs is based on physiological reasons--Explanation of the curative effects of sodium bicarbonate and sodium chloride--The causes of individual differences in the work of the digestive glands--Participation of the inhibitory nerves of secretion in the production of pathological effects.

GENTLEMEN,--To-day we shall endeavour to bring the previously communicated results of our laboratory investigations into reconciliation with the customs observed in the ingestion of food, and with the regulations prescribed by the physician in disorders of the digestive apparatus. To bring our knowledge to full fruition, and so secure for it the most useful application, the same methods should be applied from the same standpoint to the experimental investigation of the pathology and therapeutics of the alimentary canal. Nor should we be likely to encounter insuperable difficulties. Thanks to the advances of bacteriology, many of the pathological processes can now be experimentally produced in the laboratory. Moreover, we would, in a sense, have to deal with external ailments, since our present methods enable us to obtain access to any desired part of the inner surface of the digestive canal. In such pathological animals the functional diseases of the apparatus could be studied in a precise and detailed manner; that is to say, the alterations of secretory activity, the properties of the fluids, and the conditions under which they appear could be examined. On such animals therapeutic remedies could also be tested, the whole process of healing and the final result experimentally observed, while the conditions of secretory activity during every phase of the healing process could be investigated. It can hardly be doubted that scientific, that is to say ideal, medicine, can only take its proper position as a science when, in addition to an Experimental Physiology and Pathology, there has also been built up an Experimental Therapeutics. A proof that this is possible is furnished by the recent vigorous strides made by the science of bacteriology.

I have already described one of such pathological therapeutic experiments; namely, on the dog whose vagi nerves were divided in the neck. Other similar cases I can also call to mind. Our dog with the two stomachs suffered at one time from a slight and transitory gastric catarrh. It was then very interesting to observe that the pathological process (which we were usually able to wholly guard against) spread from the large to the small stomach. It manifested itself here in an almost continuous slimy secretion of very slight acidity, but of strong digestive power. At the beginning of the ailment, indeed before it became fully established, the psychic stimulation was remarkably effective (that is to say, still furnished juice in appropriate quantity), while local excitants almost completely failed. One may conceive that the deeper layers of the mucous membrane with the gastric glands were still healthy, and thus easily thrown into activity by central impulses, whilst the surface of the membrane with the end apparatus of the centripetal nerves was already distinctly damaged. I mention these, which I may call impressions rather than precise observations, because I wish to point out what a fruitful field awaits the investigator who wishes to study, with the aid of our present methods, the pathological conditions of the digestive organs and their treatment. Such an investigation is all the more desirable because clinical study of the same subject (notwithstanding the zeal devoted to it during the last ten years and the results derived therefrom) has to contend with serious difficulties. We must not forget that the sound or stomach-tube, the chief clinical instrument, is more uncomfortable than the ordinary form of gastric fistula which was previously practised on animals, and yet the physiology of the stomach, even with the aid of the latter, made no material progress for many long years. Nor is this difficult to understand. The investigator obtained through the fistula a mixture of substances from which it was difficult, or even at times impossible, to decide anything.

Hence the exact scientific study of therapeutic questions in this region still belongs to the future. But this does not exclude the probability that the newer acquirements of physiology may fruitfully influence the work of the physician. But physiology naturally can make no pretence to guide the field of medicine, since the knowledge at its disposal is incomplete and is much more restricted than that of the broad world of clinical reality. As a recompense for this, however, physiological knowledge is often able to explain the causation of an illness and the meaning of empirical curative methods. To employ a remedy the mode of action of which is not clear is quite a different thing from knowing precisely what we are doing. In the latter case the treatment of the diseased organ will be more effective because it will be better adapted to the special needs of the case. It is thus that medicine, being daily enriched by new physiological facts, will at length grow into what it ideally must become; namely, the art of repairing the damaged machinery of the human body, based upon _exact_ knowledge, or, in other words, applied physiology.

We may now return to our subject. If it be at all admitted that human instinct is the outcome of an every-day experience, which has led to the unconscious adoption of the most favourable conditions for life, it is particularly so with regard to the phenomena of digestion. The expression that physiology merely confirms the precepts of instinct is justified here more than anywhere else. It appears to me also that, in relation to the foregoing facts, instinct has often made out a brilliant case when brought before the tribunal of physiology. Perhaps the old and empirical requirement, that food should be eaten with interest and enjoyment, is the most imperatively emphasised and strengthened of all. In every land the act of eating is connected with certain customs designed to distract from the business of daily life. A suitable time of day is chosen, a company of relatives, acquaintances, or comrades assemble. Certain preparations are carried out (in England a change of raiment is usually effected, and often a blessing is asked upon the meal by the oldest of the family). In the case of the well-to-do a special room for meals is set apart, musical and other guests are invited to while away the time at meals--in a word, everything is directed to take away the thoughts from the cares of daily life, and to concentrate them on the repast. From this point of view it is also plain why heated discussions and serious readings are held to be unsuitable during meal-times. Probably this also explains the use of alcoholic beverages at meals, for alcohol, even in the lighter phases of its action, induces a mild narcosis, which contributes towards distraction from the pressing burden of the daily work. Naturally this highly developed hygiene of eating is only found in the intelligent and well-to-do classes, first, because here the mental activity is more strained and the various questions of life more burning; and secondly, because here also the food is served in greater quantity than is required for the wants of the organism. In the case of the poorer classes, where mental activity is less highly developed, the greater amount of muscular activity and the constant lack of more than sufficient nourishment insure a strong and lively desire for food in a normal manner, without recourse to any special regulations or customs. The same conditions explain why the preparation of food is so choice in the case of the upper classes and so simple in that of the lower. Further, all the accessories of the meal, which are foretastes of the actual repast, are obviously designed to awaken the curiosity and interest, and to augment the desire for food. How often do we see that a person who begins his customary meal with indifference afterwards enjoys it with obvious pleasure when his taste has been awakened by something piquant or, as we say, appetising. It was here only necessary to give an impulse to the organs of taste, that is, to excite them, in order that their activity might be later maintained by less powerful excitants, for a person who feels hungry such extra inducements are, of course, not necessary. The quelling of hunger in his case affords of itself sufficient enjoyment. It is not, therefore, without reason that it is often said that “Hunger is the best sauce.” This dictum, however, is only right up to a certain point, for some degree of appetising taste is desired by everybody, even by animals. Thus, a dog which has not fasted for more than some hours will not eat everything with equal pleasure which dogs usually eat, but will seek out the food which it relishes best. Hence the presence of a certain kind of spice is a general requirement, although naturally individual tastes differ.

This short discussion as to how different people behave with regard to the act of eating is of itself testimony that care should ever be taken to keep alive the attention and interest for food and to promote enjoyment of the repast--that is to say, that care should be taken of the appetite. Every one knows that a normal, useful food is a food eaten with appetite, with perceptible enjoyment. Every other form of eating, eating to order or from conviction, soon becomes worse than useless, and the instinct strives against it. One of the most frequent requests addressed to the physician is to restore the appetite. Medical men of all times and of every land have held it to be a pressing duty, after overcoming the fundamental illnesses of their patients, to pay special attention to the restoration of the appetite. I believe that in this they are not only animated by an endeavour to free their patients from troublesome symptoms, but also by the conviction that the return of appetite of itself will favour the restitution of normal digestive conditions. It may be said that to the same extent to which the patient wishes back his appetite the physician has effectively employed measures to restore it. Hence we have not a few remedies which are specially named “gastric tonics,” and whose action is to promote appetite. Unfortunately medical science has latterly deviated from this, the correct treatment of the appetite, and that which corresponds to the real conditions. If one reads current text-books on disorders of digestion, it is remarkable how little attention is paid to appetite

as a symptom or to its special therapy. Only in a few of them is its importance indicated, and then merely in short, parenthetic phrases. On the other hand, one may meet statements in which the physician is recommended to adopt no special means for counteracting so unimportant a subjective symptom as a bad appetite! After what I have said and demonstrated to you in these lectures, one can only designate such views as gross misconceptions. If anywhere, it is precisely here that symptomatic treatment is essential. When the physician finds it necessary, in disorders of digestion, to promote secretory activity by different remedies, this object can most certainly and completely be achieved by endeavouring to restore the appetite. We have already seen that no other excitant of gastric secretion, so far as quantity and quality of the juice are concerned, can compare with the passionate craving for food.

To a certain degree we can understand--and this contributes to an explanation of matters--how medical science of our time has come to regard so lightly the loss of appetite as a special object for treatment. Now, however, the experimental method has penetrated more and more into medical science, with the result that many pathological factors and therapeutic agents are judged of according to whether they hold good in the laboratory or not--that is to say, they are valued only in so far as they can be verified by laboratory experiments. Naturally we do not doubt that a movement in this direction indicates a great advance, but even here, as with every undertaking of mankind, things do not proceed without mistakes and exaggerations. We must not consider an event to be a mere picture of the imagination because it is not realisable under given experimental conditions. We often do not know all the essential conditions for the production of the phenomenon in question, nor are we yet able to grasp the connection between all the separate functions of life as fully as may be desired. Thus in the clinical treatment and pathology of digestion assistance was sought for in the laboratory, but nothing was there met with which had a relation to appetite, and consequently this factor was overlooked in medical practice. As stated above, the psychic gastric juice obtained only cursory mention in physiology, and this not even by all authors; and when it was noticed it was related more as a curiosity. Great importance was, on the other hand, assigned to the mechanical stimulus, the efficiency of which, now that our knowledge is more complete, has been shown to be purely imaginary. Each of the contending factors has at length been assigned its proper place, and if clinical medicine maintains her worthy desire of following out the experimental investigation of her problems, she must in actual practice accord to appetite its old claim for consideration and treatment.

But notwithstanding the indifference of physicians to appetite in itself, many therapeutic measures are based on the promotion of it. And in this the truth of empiricism makes itself irresistibly felt. When the patient is enjoined to eat sparingly, or when he is restrained from eating at all till the physician expressly permits, or again, when he is (for instance, during convalescence) removed from his ordinary surroundings and sent to an establishment where the whole life, and particularly the eating, is regulated according to physiological needs--in all these cases the physician seeks to awaken appetite, and relies upon it as a factor in the cure. In the first case, where the food is prescribed in small portions, in addition to preventing the overfilling of a weak stomach, the oft-recurrence of appetite juice, which is so rich in quantity and so strong in digestive power, is of great importance. I ask you here to call to mind one of our experiments in which food was given in small portions to a dog, and thus led to a secretion of much stronger juice than if the whole ration had been eaten at once. This was an exact experimental reproduction of the customary treatment of a weak stomach. And such a regulation of diet is all the more necessary, since, in the commonest disorders of the stomach, only the surface layers of the mucous membrane are affected. It may, consequently, happen that the sensory surface of the stomach, which should take up the stimulus of the chemical excitant, is not able to fulfil its duty, and the period of chemical secretion, which ordinarily lasts for a long time, is for the most part disturbed, or even wholly absent. A strong psychic excitation, a keen feeling of appetite, may evoke the secretory impulse in the central nervous system and send it unhindered to the glands which lie in the deeper as yet unaffected layers of the mucous membrane.

An instance of this, taken from the pathological material of the laboratory, I have already related at the beginning of this lecture. It is obvious in these cases that the indication is to promote digestion by exciting a flow of appetite juice, and not to rely upon that excited by chemical stimuli. From this point of view the meaning of removing a patient, the subject of chronic weakness of the stomach, from his customary surroundings is also plain. Take, for instance, a mentally overstrained individual, or a responsible official; how often does it happen that he cannot for a moment distract his thoughts from his daily work. He eats without noticing it, or eats and carries on his work at the same time. This often happens, particularly in the case of people who live in the midst of the incessant turmoil of great cities. The systematic inattention to the act of eating prepares the way for digestive disturbances in the near future, with all their consequences. There is no appetite juice, no “igniting juice,” or, at most, very little. The secretory activity comes slowly into play; the food remains much longer in the digestive canal than is necessary, or passes, for want of sufficient digestive juices, into a state of decomposition which irritates the mucous membrane of the alimentary canal and brings it into a condition of disease. No medicinal treatment can help such a patient while he remains surrounded by his old conditions. The

fundamental cause of his illness still continues in progress. There is only one course to pursue; namely, to take him completely away, to free him from his occupation, to interrupt the interminable train of thought, and to substitute for a time, as his only object in life, the care of his health, and a regard for what he eats. This is attained by sending the patient to travel, or by placing him in a hydropathic establishment. It is the duty of the physician to regulate not only the life of individual patients according to such rules, but also to have a care that in wider circles of the community a due conception of the importance of eating should be disseminated. This is particularly so with the Russian physician. It is precisely in the so-called intelligent classes of Russians that a proper conception of life generally is often found wanting, and where an absolutely unphysiological indifference towards eating often exists. More methodical nations, like the English, have made a species of cult of the art of eating. It is, of course, degrading to indulge excessively and exclusively in culinary enjoyments, but, on the other hand, a lofty contempt for eating is also reprehensible. As so often is the case, the best course here also lies between the two extremes.

With the establishment of mental effect upon the secretion of juice the influence of condiments enters upon a new phase. The conclusion had already been empirically arrived at that it was not alone sufficient for the food to be composed exclusively of nutrient substances, but that it should also be tasty. Now, however, we know why this is so. For this reason the physician, who has often to express an opinion upon the suitability of the dietaries of different persons, or even of whole communities, should constantly bear in mind the question of psychic secretion; that is to say, he should inquire after and learn how the food has been eaten, whether with or without enjoyment. But how often do the people who have charge of the commissariat pay attention solely to the nutritive value of the food, or place a higher value on everything else than taste? We must, further, in the interest of the public weal, direct attention especially to the feeding of children. If this or that inclination of the taste ultimately determines the relation of grown-up individuals towards food, a matter with which the commencing phase of digestion is closely linked, it would seem undesirable to habituate children solely to a nicety and uniformity of gustatory sensations. Such might effect their capabilities of adapting themselves to other conditions in after life.

The question of the therapeutic influence of the so-called bitters, it appears to me, bears the closest connection with that of appetite. After a long period of high repute these substances have been almost expelled from the list of pharmaceutic remedies. When tested in the laboratory, they were unable to justify their old and valued reputation; when directly introduced into the stomach, many of them were unable to produce a flow of gastric juice. Consequently, in the eyes of the clinician, they became greatly discredited, so that many were quite ready to discard their use altogether. Obviously, the simple conclusion was drawn that a weak digestion could only be assisted by a remedy which directly excites secretory activity. In this, however, it was forgotten that the conditions of the experiment possibly had not corresponded with the actual state of affairs. The whole question of the therapeutic importance of the bitters, however, acquires a different significance when we link it with another question, such, for instance, as how do bitters affect the appetite? It is the universal opinion of the earlier and later physicians that bitters increase the appetite, and if this be so everything is said. They are, in consequence, real secretory stimulants, since the appetite, as has many times been repeated in these lectures, is the strongest of all stimuli to the digestive glands. It is, however, not by any means strange that this had not previously been observed in the laboratory. The substances were either introduced directly into the stomachs of normal dogs or else injected into the circulation. But their action is chiefly bound up with their effect upon the gustatory nerves, and it was not, therefore, without some reason that this large group of remedies, consisting of substances of the most varied chemical composition, were grouped together mainly on account of a certain bitter taste common to them all. A person who suffers from digestive disturbance has, moreover, a blunted taste, a certain degree of gustatory indifference. The ordinary foods, which are agreeable to other people, and also to himself when in health, now appear tasteless. They not only arouse no desire for eating, but may even cause a feeling of dislike; there is no sense of taste, or at best a perverse one. It is necessary, therefore, that the gustatory apparatus should receive a strong stimulus in order to restore a normal sensation. As experience teaches, this object is most quickly attained by exciting sharp, unpleasant, gustatory impressions, which by contrast awaken the idea of pleasant ones. In either case there is no longer indifference, and this is the foundation upon which an appetite for this or that kind of food may be awakened, and here a general physiological law is illustrated. The light appears brighter after darkness, a sound louder after silence, the enjoyment of blithesome health more intense after illness, and so on. This explanation of the appetising effects of bitters proceeding from the mouth does not exclude the possibility of some such similar influence coming also from the stomach. As has been already stated in the fifth lecture, there is some reason for believing that certain impulses from the cavity of the stomach are likewise necessary for the excitation of appetite. It is possible that bitters not only act directly on the gustatory nerves in the mouth, but that they also act on the mucous membrane of the stomach in such a way that sensations are generated which contribute to the passionate craving for food. As a matter of fact, it has been confirmed by many clinicians that after the administration of bitters some such special sensations do arise in the stomach. The effect of these remedies consists, therefore, not

merely in the generation of a simple reflex, but in the production of a certain psychic effect, which indirectly excites a physiological secretory activity. The same probably applies to other substances, such as condiments. In any case, whether our explanation corresponds to the actuality or not, the question of the therapeutic effect of bitters is settled in the affirmative the moment we acknowledge that these substances awaken appetite. The problem, therefore, of an experimental investigation of bitters consists in establishing the fact that they have an effect upon the appetite. The question is a difficult one, and has not hitherto been attempted in the laboratory. It is not sufficient to hand over clinical observations to the laboratory as experimental proofs. One must have, in addition, the assurance that the investigation has been correctly carried out; that is to say, that it dealt exactly with the point under consideration. It is interesting to observe that the connection between appetite and gastric juice is by many physicians, and in many text-books of medicine, exactly reversed. Thus it is represented that some medicinal remedy calls forth a secretion of gastric juice, and this, by its presence in the stomach, awakens an appetite. Here we have to deal with a false explanation of a true fact, and that because it was not recognised that a psychic effect could by any possibility be a powerful excitant of secretory nerves. The customs of the chief meal of the day also correspond with our physiological results. After this or that _hors d'œuvre_, perhaps also with a liqueur of brandy (especially customary in Russia), both of which are designed to awaken the appetite, the repast proper begins, and, in the majority of cases, with something hot, consisting mostly of meat broth (_bouillon_, different soups, and so on). After this comes the really nourishing food--meat of different kinds served in various ways, or, in the case of poorer people, stews made with vegetables, and therefore rich in carbohydrate material. This sequence of foods, from the standpoint of physiology, is quite rational. Meat broth, as we have already seen, is an important chemical excitant of gastric secretion. An attempt is therefore made in two ways to secure a free secretion of gastric juice to act on the chief food; first, in the excitement of the appetite juice by the _hors d'œuvre_, and secondly, in the promotion of the flow by the action of the meat broth. It is in this way that human instinct has made provisions for the digestion of the chief meal. A good meat broth can only be afforded by well-to-do people, and consequently with the poorer classes a less expensive, and, indeed, also a less effective, chemical excitant is used for awakening the early secretion. For example, _kwas_[31] serves in this way with the Russian population, while in Germany, where the price of meat is high, different kinds of soups are used, consisting of water mixed with flour, bread, etc. It is further to be borne in mind that the quantity of the digestive juices in general stands in close connection with the content of water in the organism. This has been shown by the experiments of Dr. Walther for the pancreatic juice, and by my own for the gastric juice. If this sequence of foods, therefore, holds good for healthy people, it must be even more strictly adhered to in pathological conditions. Thus, when a person has no appetite, or only a weak one, he has no psychic juice or only very little; consequently, the meal must in every case be begun with a strong chemical excitant--for example, with a solution of the extractives of flesh. Otherwise solid foods, particularly if they do not consist of meat, would remain long in the stomach without any digestion whatever. It is, therefore, in every way desirable to prescribe meat juice, strong broth, or meat extract to people who have no appetite. The same applies also to forced feeding, for instance, of the insane. It is true that the method of introduction in this case necessarily secures the presence of a chemical excitant, since the food can only be introduced in a fluid form. In any case the addition of meat extract would be very useful. If one arranged the ordinary fluid foods in descending order, according to the influence of the chemical excitants, the following would be the series: first, the preparations of the flesh, such as meat juice and the like; secondly, milk; thirdly, water.

The usual termination of the repast is also, from the physiological standpoint, easy to be understood. The chief meal is generally ended with something sweet, and everybody knows that sweets are pleasant. The meaning of this is easy to guess. The repast, begun with pleasure, consequent on the pressing need for food, must also, notwithstanding the stilling of hunger, be terminated with an agreeable sensation. At the same time the digestive canal must not be burdened with work at this stage; it is only the gustatory nerves which should be agreeably excited. After thus dealing in general with the usual arrangement of our meals, we may now speak of some special points.

Above all comes the acid reaction of the food. It is apparent that acidity enjoys a special preference in the human taste. We use quite a number of acid substances. Thus, for example, one of the commonest seasoning substances is vinegar, which figures in a number of sauces and such like. Further, many kinds of wine have a somewhat acid taste. In Russia, _kwas_, especially in the acid form, is consumed in great quantities. Moreover, acid fruits and green vegetables are used as food, and they are either of themselves acid, or made so in the preparation. In medicine this instinct is likewise often made use of, and acid solutions, especially of hydrochloric and phosphoric acids, are prescribed in digestive disturbances. Finally, Nature itself constantly endeavours to prepare lactic acid in the stomach in addition to the hydrochloric acid. The former arises from the food introduced, and is consequently always present. These facts are all physiologically comprehensible when we know that an acid reaction is not only necessary for an efficient action of the peptic ferment, but is at the same time the strongest excitant of the pancreatic gland. It is even conceivable that in certain cases the whole digestion may depend upon the stimulating properties of acids, since the

pancreatic juice exerts a ferment action upon all the constituents of the food. In this way acids may either assist digestion in the stomach where too little gastric juice is present, or bring about vicarious digestion by the pancreas where it is wholly absent. It is easy, therefore, to understand why the Russian peasant enjoys his _kwas_ with bread. The enormous quantity of starch which he consumes, either as bread or porridge, demands a greater activity upon the part of the pancreatic gland, and this is directly brought about by the acid. Further, in certain affections of the stomach, associated with loss of appetite, we make use of acids, both from instinct as well as medical direction, the explanation being that they excite an increased activity of the pancreatic gland, and thus supplement the weak action of the stomach. It appears to me that a knowledge of the special relations of acids to the pancreas ought to be very useful in medicine, since it brings the gland--a digestive organ at once so powerful and so difficult of access--under the control of the physician. We could, for instance, intentionally discard digestion in the stomach, and thus transfer it to the bowel, by prescribing substances which do not excite the gastric glands. On the other hand, by lessening the acidity of the gastric juice we could reduce the activity of the pancreas, and these are matters which might be made use of in various special diseases, or even in some general disturbances of the digestive apparatus.

No less instructive is a comparison of the results of our experiments upon fat, with the demands of instinct and also with the precepts of dietetics and therapeutics. Everybody knows that fatty foods are heavy, that is, difficult of digestion, and in the case of weak stomachs they are usually avoided. We are now in a position to understand this physiologically. The existence of fat in large quantities in the chyme restrains in its own interest the further secretion of gastric juice, and thus impedes the digestion of proteid substances; consequently, a combination of fat and proteid-holding foods is particularly difficult to digest, and can only be borne by those who have good stomachs and keen appetites. The combination of bread and butter is less difficult, as might _a priori_ be inferred from its wide employment. Bread requires for itself, especially when calculated per unit, but little gastric juice and but little acid, while the fat which excites the pancreatic gland insures a rich production of ferment both for itself and also for the starch and proteid of bread. Fat alone does not count by any means as a heavy food, as may be seen from the fact that large quantities of lard are consumed in certain districts of Russia with impunity. This also is comprehensible, since the inhibitory influence of the fat in this case does not prevent the digestion of any other food-stuff, and is conducive to the assimilation of the fat itself. There is no struggle in this case between the several food constituents, and therefore no one of them suffers. In harmony also with daily experience the physician, in cases of weakness of the stomach, totally excludes fatty food and recommends meat of a fat-free kind; for example, game, etc. In pathological cases, however, where an excessive activity of the gastric glands is manifested, fatty food, or fat as emulsion, is prescribed. And here medicine has empirically brought to its aid the restraining action of fat, which we have so strikingly seen in our experiments.

Amongst all the articles of human food, milk takes a special position, and this is unanimously recognised, both in daily experience and in the practice of medicine. By everybody milk is considered a light food, and is given in cases of weak digestion as well as in a whole series of severe illnesses; for example, in heart and kidney affections. The extreme importance of this substance, a food prepared by Nature itself, we can now well understand. There are three properties of milk which secure it an exceptional position. As we already know, in comparison with nitrogenous equivalents of other foods, the weakest gastric juice and the smallest quantity of pancreatic fluid are poured out on milk; consequently, the secretory activity requisite for its assimilation is much less than with any other food-stuff. In addition, milk possesses a further important property. Thus, when it is introduced unobserved into the stomach of an animal it causes a secretion both in the stomach and also one from the pancreas; consequently, it appears to be an independent chemical excitant of the digestive canal; and in this action it is remarkable that we perceive no essential difference in the effect when the milk is brought unnoticed into the stomach from that which occurs when it is given to the animal to lap. Although flesh is a better chemical excitant, it is by no means a matter of indifference how it gets into the stomach. It must, therefore, be accepted that milk excites not only a really effective, but at the same time a very economic, secretion, and also that the appetite is unable to stimulate this secretion into a more active or abundant flow. The secret of the relation of milk to the secretion of the digestive juices can, unfortunately, at present be submitted to no further analysis or investigation. We are at liberty, however, to suppose that the fat on the one hand is of importance for the inhibition of the gastric glands, and the alkalinity on the other for the restraint of the pancreas. Thus the gastric glands and the pancreas, notwithstanding the presence of excitants, are maintained by milk at a certain but not too high degree of activity, a matter which is in every way desirable in consideration of the easy digestibility of its constituents. Finally, the third characteristic which is observed to belong to milk, and which is probably only an expression of the first, consists in the following. When one administers to an animal equivalent quantities of nitrogen, in the one case as milk, in the other as bread, and afterwards estimates the hourly output of nitrogen in the urine, it results that the increase during the first seven to ten hours after the milk (compared with the excretion beforehand) amounts only to from 12 per cent to 15 per cent of the nitrogen taken in, while after bread it amounts to 50 per cent. If the hourly rate of absorption and the extent to which milk and bread

are respectively used up be taken into consideration, it has to be admitted that these augmentations of urinary nitrogen which appear soon after feeding must be expressions of the functional activity of the digestive canal itself, and that this activity in the case of bread is three or four times greater than in the case of milk (_Experiments of Prof. Rjasanzew_); consequently, in the case of milk a much larger fraction of its nitrogen is free to be used up by the organism at large (irrespective of the organs of digestion) than in that of any other kind of food. In other words, the price which the organism pays for the nitrogen of milk, in the form of work on the part of its digestive apparatus, is much less than that for other foods. How admirably, therefore, the food prepared by Nature distinguishes itself when compared with all others!

The facts just related bring forward a new aspect from which the relative nutritive values of different foods may be judged. The older criteria must frankly make room for the new or else be displaced by them. Experiments upon the utilisation of food-stuffs, in which what remains undigested is determined as well as what is absorbed into the body fluids, cannot alone be trusted to solve the question in a satisfactory manner. Suppose, for instance, that in the digestion of a given food the alimentary canal has been given a certain work to perform; if it be in health the work will be accomplished in the best possible manner--that is to say, with complete abstraction of everything nutrient. You will thus learn how much nutrient material was contained in the food, but the question of its digestibility remains as obscure as before. In your experiment you do not know how great an effort it has cost the alimentary canal to extract all the nourishment from the food. Nor can artificial digestion experiments settle the question of digestibility, for experiments in which food is normally partaken of are quite different from those in the test-tube, where we have to deal with only one juice, and not with the interaction of different juices and different food constituents. That one must here, as a matter of fact, make a distinction is clear from the observation of Dr. Walther in our laboratory. Fibrin, which is regarded by all as the most easily digested proteid, proved, when compared with a nitrogen equivalent of milk, to be a much stronger excitant of the pancreas, although milk contains, in addition to nitrogenous substances, a good deal of other non-nitrogenous material. The digestibility and nutritive value of foods must obviously be decided by an estimation of the real work which they entail upon the digestive apparatus, both in regard to the quantity and quality of the juices poured out on a given amount of nutrient material. The energy used up in gland metabolism must be deducted from that of food taken in. The remainder will then indicate the value of the food to the organism; that is to say, will give the amount available for use by all the other organs exclusive of the digestive apparatus. From this point of view those materials must be taken as less nourishing and less digestible which are in large part used up to make good the expenditure entailed by their digestion on the part of the alimentary canal; that is to say, those food-stuffs are less useful whose nutritive value little more than covers the cost of their digestion; consequently, it is of great practical importance to compare from this aspect the same foods differently prepared--for example, boiled and roast meat, hard and soft boiled eggs, boiled and unboiled milk, etc.

A discussion of some further medical questions may here be taken up. The first concerns the therapeutic use of the neutral and alkaline salts of sodium. In clinical, pharmacological, and physiological text-books it is stated now, as ever, that these salts promote a flow of gastric juice. We may look in vain, however, for any experimental foundation to support this doctrine. The experiments brought forward cannot be regarded as conclusive. When Blondlot sprinkled sodium bicarbonate upon flesh, or Braun and Grützner introduced sodium chloride solutions directly into the blood, they began with methods either false in themselves or far removed from normal conditions. In this case, however, the gaps in the experiment were happily made good by the clinician, for the experiment appeared to be confirmatory of clinical experience. That sodium salts (the chloride and bicarbonate) are useful in disorders of the digestive apparatus there can be no doubt. How do they act, however? It appears to me that here, as in some other cases, medical science has fallen into error. When we know that an effect takes place it does not by any means imply that we know the mechanism by which it occurs; and although medicine is broad enough and comprehensive enough to make free use of empiricism in practice, yet it often thinks in narrow grooves when it turns to the explanation of facts. It frequently tries to explain complicated healing processes in the simplest way, on supposed physiological data. And this is true in the present case, which affords an example of prevalent medical reasoning; the alkalies work favourably in digestive disturbances--therefore they are succagogues. Naturally the stomach, under the influence of alkalies, sometimes begins to secrete a greater quantity of juice. This means, however, that it has recovered from a disordered state and has returned to normal conditions. Consequently, the effect is due to the fact of recovery, and not to a direct influence of the alkalies. This latter, however, must be specially proved. The assistance afforded by the alkalies to the organism might be capable of another explanation; for example, that which is ordinarily given. In this case, however, I venture to offer a reason for the effects of sodium chloride, and of the alkaline salts of sodium, which is exactly the opposite of that generally accepted. We were unable to convince ourselves of any succagogue influence on the part of these salts. Indeed, both on the stomach and pancreas they proved in our hands to have an inhibitory effect. In addition to the experiments which I previously brought forward concerning the relation of alkalies to gastric and pancreatic juice, I may relate the

following observation. A dog which fortunately had survived the performance, one after the other, of a gastric fistula, a pancreatic fistula, and an œsophagotomy, received daily during the course of several weeks an addition of soda to its food. The animal enjoyed good health and had an excellent appetite. When the first sham feeding experiment was carried out, the relatively small effect of this otherwise very active juice-exciting procedure at once struck us. At the same time we observed that the pieces of flesh which fell from the upper end of the œsophagus, contrary to the ordinary rule, were hardly at all insalivated. In this dog, therefore, a greatly lowered activity of several digestive glands--viz., of the gastric, pancreatic, and salivary glands--simultaneously existed. With regard to the salivary glands the circumstance was naturally submitted to closer investigation. I believe that the inhibitory influence of the alkalies on the digestive glands, which was here proved experimentally, may furnish a basis for the following representation of their mode of action in producing healing effects. Catarrhal affections of the stomach are characterised by an incessant or very protracted secretion of slimy, weakly acid gastric juice. Further, in many cases the affection begins with a hypersecretion, that is an abnormal excitability, of the secretory apparatus which makes itself evident in a superfluous and useless flow. The same must be conceived to happen in disorders of the pancreatic gland; at least such a condition sets in after operations performed for physiological purposes. It is, further, justifiable to suppose that, when an affection is once set up by this or that cause, it may later maintain itself independently; for continuous activity has undoubtedly a harmful influence on the glands. The due nourishment, and the restoration of organs after activity, proceeds best during rest. In the normal course of events, after a period of active work follows a pause, during which the latent work of restoration is accomplished. When, therefore, a remedy effectively restrains the excessive work of a diseased organ, it may in this way contribute to the removal of the pathological condition, and thus to a restoration of the normal state. In this consists, in my opinion, the healing effects of the alkalies. One might draw a parallel between the action of these substances in digestive disturbances and that of digitalis in compensatory disturbances of the heart. An uncompensated heart beats rapidly, and thereby only aggravates its condition. Its time of rest, that is of recovery, of restitution of the organ, is shortened. A vicious cycle is set up. The weak action of the heart lowers blood pressure; the lowering of this leads (from known physiological causes) to an increase in the number of beats; the quickening leads to weakening of the organ. Without doubt the digitalis aids by breaking through this vicious cycle, in that it greatly slows the pulse, and thereby gives new power to the heart. With our explanation of the action of the alkalies harmonises the further circumstance that, with the use of the salts in question, a strict diet is generally prescribed, which means that a certain amount of rest is secured for the digestive glands. It is interesting that in clinical investigations with the stomach-tube, after a period when the alkalies were looked upon as succagogues, a new phase has also set in, mention being now more frequently made of a restraining effect.

The cause of the erroneous belief that alkalies promote a flow of juice obviously lies in this, that people omitted to compare the effects of the saline solutions with those of like quantities of water (_Dr. Chigin_).

The second point which we may consider is the following. The chief difficulty of the physician who wishes to regulate the diet of patients when they suffer from digestive disturbances consists in the fact that idiosyncrasy plays a very important _rôle_. In one and the same illness, different patients react to the same diet in wholly different ways. That which is agreeable to one, and is well borne and useful, may be rank poison to another. Consequently, the golden rule in dietetics is to give no directions with regard to food till one has made inquiries concerning the inclinations and habits of the patient. What does all this indicate? Till now physiology had no experimental answer to the question. But our facts, it appears to me, contribute to a clearing up of the situation. Every food determines a certain amount of digestive work, and when a given dietary is long continued, definite and fixed types of glands are set up which can only slowly and with difficulty be altered. In consequence, digestive disturbances are often instituted if a change be suddenly made from one dietetic _régime_ to another, especially from a sparse to a rich diet; such, for instance, as happens after the long Russian fasts. These disturbances are expressions of the temporary insufficiency of the digestive glands to meet the new demands made upon them.

Finally, it may be of some use to relate the following here. There are often cases of sudden and unaccountable digestive disturbances. From the standpoint of modern physiology they might be explained by an activity of the secreto-inhibitory nervous system, which from some cause or other has been excessively and abnormally stimulated. In any case this system is now a factor of which the physician has to take due account.

SWALLOWING AND MOVEMENTS OF THE STOMACH AND INTESTINES

BY W. B. CANNON, M.D.

Of the Physiological Laboratory of the Harvard Medical School Boston, Mass., U. S. A.

[NOTE.--In the beginning of 1896 Dr. Professor Henry Pickering Bowditch, one of our Board of Scientific Assessors in the Nutrition Case suggested the use of the Röntgen ray as a means of learning more than was then known about the mechanism of swallowing. There was much difference of opinion among research physiologists about this important function, and the question was far from settled. Magendie published a theory of deglutition, in Paris, in 1836, which was practically accepted until 1876, when Dr. Professor Angelo Mosso, of the University of Turin, Turin, Italy, established the theory of sole peristaltic assistance in swallowing. Again in 1880 Dr. Professor Kronecker, of Berne, Switzerland, in connection with Dr. Falk, and later in connection with Dr. Meltzer, of New York, produced evidence to prove a more complicated process in deglutition than that of peristalsis alone. But even Kronecker and Meltzer found, as they went on, evidence to modify their earlier beliefs, and hence the subject was not cleared up to a point of general agreement.

The suggestion made by Dr. Bowditch was taken up in the Harvard Physiological Laboratory and formed the beginning of a series of studies of the mechanical factors in digestion. The reports of these studies, presented by Dr. W. B. Cannon and collaborators, in the _American Journal of Physiology_, in the volumes of 1898 and 1903, are so understandable, even to the layman ignorant of physiological nomenclature, that we are prompted to give them, almost entire, leaving out only the technical description of the methods employed, which are only interesting to research students who have access to the _Journal_.

It will be noted that three of the professors of physiology mentioned in connection with this preliminary study of the nutrition problem--Bowditch, Mosso, and Kronecker--are members of our presently organised Board.—HORACE FLETCHER.]

THE MOVEMENTS OF THE FOOD IN THE ŒSOPHAGUS

BY W. B. CANNON AND A. MOSER

From the Laboratory of Physiology in the Harvard Medical School

Extracts from _American Journal of Physiology_, 1898

The movements of deglutition, in common with many other physiological processes, were explained by the older physiologists on anatomical grounds. Thus, Magendie divided the act into three parts, corresponding to the anatomical regions of the mouth, pharynx, and œsophagus. The muscles of each of these divisions were considered the active agents in propelling the food onward. The function of moving the mass to the pharynx was variously ascribed to the tongue itself, to the mylohyoid muscles, and to gravity. For the second part, the movement through the pharynx, there was more unanimity of opinion, since the constrictors, especially the middle and lower, were evidently concerned.

Direct observations on the movement of swallowed masses in the œsophagus were first made by Mosso. The œsophagus of a dog was laid bare, and a transverse incision made through it, or a piece of it excised. A small wooden ball was placed in the canal below the excised part, and the animal was then stimulated to swallow. One or two seconds after the contraction of the pharyngeal muscles a peristaltic wave began to traverse the œsophagus. This wave did not stop at the point of excision, but in due time reappeared below, and carried the ball to the stomach. Thus the act was shown to be controlled by the central nervous system. Peristalsis was so plainly the motive power that the action was never doubted. Yet this belief was soon to be questioned.

In 1880 Falk and Kronecker studied the movements in the mouth and pharynx, and advanced the theory that deglutition was accomplished by the rapid contraction of the muscles of the mouth. During the act of swallowing the air-tight buccal cavity shows a manometric pressure of twenty centimetres of water. The same pressure was demonstrated to be present also in the œsophagus, but not in the stomach. This pressure was considered sufficient to force food through the œsophagus before the peristaltic wave traversed it. Another argument for rapid descent was found in the fact that cold water can be felt in the epigastric region almost immediately after being swallowed. Further, when strong acids pass through the gullet, they corrode but small parts of it, and not the entire mucous membrane, as would be the case were the acid carried to the stomach by peristalsis.

Over a year and a half ago it was suggested by Prof. H. P. Bowditch that if some substance opaque to the Röntgen rays were swallowed, it could be seen in its passage to the stomach, and the nature of its movement thus determined. Anæsthesia could be dispensed with,--a desirable condition, since observers had found that it interfered greatly with the deglutition reflex. It would be unnecessary to open either the abdominal or the pleural cavity. The reflex stimulus of food, moreover, would be better than electrical stimulation of the superior laryngeal nerve. In short, the animal would swallow normal food under practically normal conditions. At Dr. Bowditch's suggestion and with his valuable assistance--which we gratefully acknowledge--we made the

following series of experiments.

To render the swallowed mass opaque, subnitrate of bismuth was used. The salt is tasteless, practically inert, and can be fed in large quantities without harm. In order that observations could be made by more than one person, all experiments were conducted in a dark room. On the side of the animal opposite the Crookes tube was placed an open fluorescent screen, on which the different tissues of the animal were outlined with varying degrees of light and shade. Among these shadows the swallowed mass appeared as a darker object, and thus its motion could be studied.

For the first experiments the goose was selected. The head and neck were held stationary by a tall pasteboard collar, which allowed free movement of the head without constriction of the neck. The fluorescent screen was placed against this collar at a uniform distance of thirty centimetres from the tube. When a bolus of corn-meal mush mixed with bismuth was placed in the pharynx, it descended slowly and regularly, and occupied about twelve seconds in passing over a distance of fifteen centimetres. The screen was marked at intervals of two centimetres with cross lines, by means of which the relative rate in different parts of the œsophagus could be studied. A vibrator marking tenths of a second was interrupted whenever the bolus crossed a line. An average of over one hundred such observations showed that the rate became slightly slower as the bolus proceeded.

In order to test liquids, molasses was mixed with bismuth to such a consistency as to drop easily from a glass rod. When this was fed with a pipette, it passed slowly and regularly down the œsophagus, clearly by peristalsis. The rate was about the same as for solid food. In both these experiments the addition of water would sometimes cause irregularities in the descent. Microscopic sections from four different parts of the œsophagus of the goose showed no histological difference.

In the experiments on the cat, the animal was placed on its back and left side on a holder. The extremities were secured by straps. The head was held between two upright rods, connected above by a thong; this allowed free movement of the head, without resistance to the passage of food. Shreds of meat dipped in bismuth were ordinarily masticated and swallowed without difficulty. For soft solids, bread and milk were used, so fluid as to be easily drawn up into a pipette. The insolubility of the bismuth salt rendered the study of liquids more difficult. Strong solutions of potassic iodide and other salts, and suspension of bismuth, in acacia and molasses were tried; but a simple mixture of milk and bismuth, shaken in a test tube and immediately drawn up into a pipette, was found most practicable.

Inasmuch as the movement of these different foods varied in different parts of the œsophagus, it will be convenient to divide the latter into three sections. The first or cervical portion extends from the pharynx to the thorax; the second or thoracic, from here to the lower half of the heart; and the third comprises the rest of the canal. The relative length of these three parts is about in the ratio of 9:8:6.

The beginning of deglutition was noted by one observer by a finger on the larynx; the same observer called out when the bolus arrived at the thorax, heart, and stomach respectively, while the other observer noted the time. The movement of solids will first be considered. The descent the entire way was by peristalsis, but the rapidity varied. The duration of the movement in the cervical portion was two and a half seconds, and in the thoracic region a little less than two seconds. At the lower end of the heart there was sometimes a slight pause. In the lower section, from the heart to the stomach, the movement was decidedly different; the rate was always very slow. The distance was less than one-third of the entire canal, yet the time consumed in this part ranged from six to seven seconds, or three-fifths of the entire time of descent. The character of the movement here was also peculiar. Whereas in the upper sections the passage was uniform and regular, with a slight acceleration in the thoracic region, here it was apparently irregular, for the bolus descended about one centimetre with each inspiratory movement of the diaphragm, and remained stationary or descended very slightly during expiration. Thus a series of hitches seemed to carry the bolus to the cardia. A probable explanation of this peculiar movement is that the stomach and lower œsophagus were pulled down with each descent of the diaphragm. This would make the movement appear irregular, although it was really a slow peristalsis. It may be well to remark here that this movement was invariably observed in the cat with every kind of food.

Semi-solids, namely, a mush of bread and milk, descended in the same way as solids; but the rate was slightly faster in the upper œsophagus, for the bolus took about a second less to reach the cardiac level. From here the rate was the same as with solids.

For liquids, one and a half to two seconds sufficed for the descent to the midheart region. Here there often occurred a long pause, from a few seconds to a minute or more. Then the œsophagus apparently contracted above the liquid, which slowly passed on to the stomach, as already described. Sometimes it seemed as if a swallowing movement, evidenced by a rise of the larynx, started the peristaltic wave. Again, several swallows would succeed one another before the liquid passed on. A few times the bismuth and

milk seemed strung out along the œsophagus; some more liquid descending would gather this up, and the whole mass, assuming an ovoid form, would move into the stomach.

Thus in the cat the total time for deglutition varies from nine to twelve seconds. The lowest section presents no change ascribable to a difference in consistency, while in the upper sections the rate does slightly increase with the more liquid character of the food.

In experiments on the dog, bismuth enclosed in capsules or wrapped in shreds of meat was fed as the solid. The general phenomena were as follows: With the rise of the larynx there was a quick, propulsive movement of the bolus, which descended rapidly for a few centimetres, sometimes as far as the clavicle. From this point the rapidity was diminished, yet no pause was observed; the bolus simply moved more slowly. This rate was then continued to the stomach without a slackening of speed in the diaphragmatic region, as was observed in the cat. Semi-solids moved in the same way as solids. The total time of descent from larynx to stomach was from four to five seconds.

Liquids gave even a more decided squirt in the beginning of the movement. To render the œsophagus as lax and free as possible, the head of the dog was released from the upright rods and held by the hands after the food was placed in the mouth. Sometimes the liquid descended rather rapidly as far as the heart, at other times no further than the clavicle; then without a pause it passed on slowly and regularly, reaching the stomach in about the same time as solids and semi-solids.

Thus in the dog and cat but little variation was seen in the swallowing of liquids and solids. The liquids pass somewhat faster in the upper œsophagus. But in some animals the difference of rate with foods of varying consistency is much more marked. In the horse, for instance, mere observation shows a decided variation in the rate of movement in the œsophagus. Liquids shoot along the gullet, while solids move clearly by peristalsis. To determine the rate of solids, one hand was placed on the larynx of a horse to note the beginning of swallowing, and the other hand near the shoulders, where the bolus could be easily felt in its passage. The time consumed by the bolus in passing over a certain distance was measured by a stop watch. The rate obtained for solids, such as hay or grain, was from thirty-five to forty centimetres a second.

For semi-solids, a mixture of bran and water was made, thin enough to run easily between the fingers. Each bolus was watched by a separate observer with a separate watch. The average rate obtained was the same as for solids.

Liquids in the horse pass with a rapidity too great to be affected by peristalsis. Another force must be sought. Among the various muscles supposed to be effectual in moving food into the pharynx, the mylohyoids were shown by Meltzer to be essential. The styloglossi were cut by him without much interference with deglutition, but section of the mylohyoid nerves rendered the act impossible. The activity of these muscles in the horse during swallowing is easily perceived by the hand. Their energetic contraction is a sufficient explanation of the rapid passage of water through the œsophagus. The motion here is more than five times as rapid as that of solids and semi-solids.

Meltzer’s experiment to measure the rate of liquids in man by passing a stomach tube containing litmus paper was repeated by us with some modifications. Congo red paper was used, since it is more sensitive than litmus; it also furnishes a means of differentiating between mineral and organic acids, as the discolouration produced on Congo red by mineral acids is removed by ether. It was thus possible to distinguish between the discolouration produced by gastric regurgitation and that produced by the swallowed liquid. For the swallowed liquid, one-half per cent lactic acid was found most satisfactory, as the colour produced by it on Congo red test paper is almost instantly discharged in ether. By this method the paper was found discoloured within half a second after the rise of the larynx, certainly too short a period for a peristaltic wave to carry the liquid to the neighbourhood of the cardia.

The X-ray method lends itself less successfully to the study of deglutition in man than in the other animals we have studied. The thickness of the thorax, the distance of the œsophagus from the surface, and the relation to dense tissues render the observation of a swallowed mass difficult, especially when the mass is in rather rapid motion. The few observations which we have to report were made on a seven-year-old girl, placed in the sitting posture. Gelatine capsules containing bismuth were used for solids, and were traced to a point below the heart. The motion was very regular, and apparently due to peristalsis, for the bolus descended without a hitch or irregularity of any kind. Sometimes the capsule became fixed in the upper œsophagus, at about the level of the second rib. Repeated swallows of water would fail to dislodge it. An interesting point was noted here. With each attempt at swallowing, the capsule would rise slightly, as if the œsophagus was pulled up with the rise of the larynx; then the capsule would descend to its former position.

Semi-solids--a mush of bread and milk--could be seen about as far as solids; that is, to just below the heart. The motion of the mushy bolus was the same as with solids, except that the rapidity was perhaps slightly greater.

It should be noted here that with the human subject, as well as with the horse, our results for semi-solids differ from those derived by Meltzer's method; for according to his statements semi-solids, like liquids, are squirted down the œsophagus, and are not propelled by peristalsis, as has been the case in our observations.

Liquids--bismuth and water--were seen only in the neck and upper thorax. Here there was a decided squirt. With the rise of the larynx the liquid was seen to pass rapidly through the pharynx and well down into the thoracic œsophagus before it was lost to observation. The rate, however, by estimation was less than that of liquids in the horse.

There remains to be considered Meltzer's latest investigation, in which he endeavoured to ascertain whether liquids remain above the cardia till the arrival of the peristalsis, or ooze down before. An experimental answer was secured by Meltzer by the following method. The abdominal and gastric walls of an anæsthetised dog were incised, and a tube (vaginal speculum) introduced. Through this the entrance of food into the stomach could be observed directly. In repeated experiments no liquid was seen to pass through the cardia before the arrival of the peristaltic wave. An incision through the diaphragm near its anterior origin showed that the swallowed liquid was not squirted as far as a point an inch above the diaphragm. To observe the œsophagus nearer its beginning, the upper three ribs were resected on the left side. Thus the swallowed liquid was seen to shoot along the œsophagus before any peristalsis reached this point. The resection of the fifth rib exposed the œsophagus half-way between the bifurcation of the trachea and the diaphragm. Here a bulging was sometimes observed immediately after the beginning of the act, and the swallowed mass remained there until a peristaltic wave carried it down. If the mass swallowed was small, or was projected with moderate force, it might not even reach as far as the bifurcation. From these experiments Meltzer concluded that in animals, as in man, liquid food is not carried down the œsophagus by peristalsis, but is thrown rapidly into a deep part of the canal. The depth reached depends on the quantity swallowed, the force used, and the tonicity of the lower part of the œsophagus.

The difference between these methods of Meltzer and those employed in our experiments has already been mentioned; and merely his results, which were obtained with liquids alone, need be considered here. According to our observations on the dog, there was no distinct pause at any part of the canal. The movement simply became slower, and continued at this rate until the stomach was reached. Neither was the rate through the diaphragmatic part of the œsophagus slower than through the thoracic. The quick propulsive movement noticed in the dog was observed with solids and semi-solids as well as with liquids, but the liquids descended further down the canal before the movement changed to the slower peristalsis. While this difference was evident to the eye, the total time consumed by liquids in passing from pharynx to stomach was not enough shorter than the time for solids and semi-solids to be determined by our measurements.

SUMMARY.

The phenomena of œsophageal deglutition as determined by our experiments may then be described as follows:—

There is a difference in swallowing according to the animal and the food which is used.

In fowls the rate is slow and the movement always peristaltic, without regard to consistency. A squirt-movement with liquids is manifestly impossible, as the parts forming the mouth are too hard and rigid. With this diminution of propulsive power in the mouth there is observed a greater reliance on the force of gravity. The head is raised each time after the mouth is filled, and the fluid by its own weight trickles into the œsophagus, through which it is carried by peristalsis.

In the cat the movement is always peristaltic, and slightly faster than in fowls. A bolus takes from nine to twelve seconds in reaching the stomach. Liquids move somewhat more rapidly than semi-solids in the upper œsophagus. In the lower or diaphragmatic part the rate is very much slower than above, and is the same for liquids as for solids.

In the dog the total time for the descent of a bolus is from four to five seconds. The food is always propelled rapidly in the upper œsophagus, and moves more slowly below. This rapid movement is frequently continued further with liquid food. No distinct pause was observed when the movement of the bolus changed from the rapid to the slower rate.

In man and the horse liquids are propelled deep into the œsophagus at a rate of several feet a second by the rapid contraction of the mylohyoid muscles. Solids and semi-solids are slowly carried through the entire œsophagus by peristalsis alone.

THE MOVEMENTS OF THE STOMACH STUDIED BY MEANS OF THE RÖNTGEN RAYS

BY W. B. CANNON, M.D.

From the Laboratory of Physiology in the Harvard Medical School

Extracts from _American Journal of Physiology_, 1898

Since the stomach gives no obvious external sign of its workings, investigators of gastric movements have hitherto been obliged to confine their studies to pathological subjects or to animals subjected to serious operative interference. Observations made under these necessarily abnormal conditions have yielded a literature which is full of conflicting statements and uncertain results. The only sure conclusion to be drawn from this material is that when the stomach receives food obscure peristaltic contractions are set going, which in some way churn the food to a liquid chyme and force it into the intestines. How imperfectly this describes the real workings of the stomach will appear from the following account of the actions of the organ studied by a new method. The mixing of a small quantity of subnitrate of bismuth with the food allows not only the contractions of the gastric wall, but also the movements of the gastric contents to be seen with the Röntgen rays in the uninjured animal during normal digestion. An unsuspected nicety of mechanical action and a surprising sensitiveness to nervous conditions have thereby been disclosed.

INTRODUCTORY LITERATURE

The early writings on the subject of gastric movements are characterised by general inferences from physical laws and from the anatomical structure of the stomach. According to Galen the stomach had four functions: to draw the food from the mouth (_facultas attractrix_), to retain the food (_facultas retentrix_) during the process of chemical digestion (_facultas alteratrix_), and, finally, to pass the changed material onward (_facultas expultrix_). In later writings the _facultas attractrix_ failed to appear as one of the functions of the stomach. Fallopius, in the sixteenth century, changed the notion of the _facultas retentrix_ by suggesting that the pylorus alone performed this office, and that the muscles of the gastric wall could help only by remaining quiet. Thus the _facultas alteratrix_ and the _facultas expultrix_ are left as true gastric functions. It is with the latter activity and its effects that this paper is concerned.

The ideas of the early writers concerning the pylorus and cardia are of interest. The cardia, they were agreed, is closed during normal digestion in order to keep the food from re-entering the œsophagus. The pylorus they looked upon as the ruler of the actions of the stomach. Such names as pylorus (keeper of the gate), janitor justus, and rector, which the first investigators gave to the sphincter, indicate their theories of its functions. The passage of chyme into the duodenum, the keeping of undigested food in the stomach, the act of vomiting, were all dependent, they believed, on the “will” of the pylorus.

No substantial advance was made beyond these hypotheses until the beginning of the eighteenth century, when Wepfer and Schwartz applied the experimental method to the study of the gastric movements and laid the foundation of a more accurate knowledge. Wepfer vivisected wolves, dogs, and cats, and observed constrictions following stimulation of the stomach. He remarked a general contraction of the pyloric part in vomiting and noted peristaltic and antiperistaltic movements passing over the organ. About the middle of the stomach he frequently saw a deep constriction. The investigations of Schwartz are more valuable in that his search was for the normal action of the muscular coats. The movements, as he observed them, were generally only slight. They began either at the pylorus and passed to the left, half-way to the cardia, or started at the fundus and went to the pylorus. The contractions and relaxations, following one another, formed larger or smaller depressions and elevations, _i. e._, more or less definite waves.

Near the middle of the last century Haller, after confirming the results obtained by Schwartz and Wepfer, summarised his knowledge of the motor functions of the stomach as follows. In general, contraction alternates with relaxation, so that the stomach is, now here, now there, made narrower by longitudinal or transverse depressions; then in these same places relaxation and bulging occur. So long as both apertures are closed the food is driven hither and thither by the shifting movements. It first takes a definite direction when the cardia or the pylorus opens. If the cardia opens, there is an antiperistalsis followed by regurgitation and vomiting. If, on the contrary, the pylorus relaxes, a contraction, starting at the œsophagus, pushes the contents of the stomach into the duodenum. The pylorus allows the passage of fluids, but if it be stimulated by over distention or by hard pieces of food, it closes tightly.

Such was the knowledge of gastric movements in Haller's time. A comparison of his descriptions with those in any standard work on physiology published ten or fifteen years ago will show that, despite very many researches, little advance had been made. Examinations of animals and men with gastric fistulas, studies of the stomach through the atrophied abdominal wall, and vivisection have yielded numerous results; but these have not been harmonious, and have led to much controversy. Prominent in this mass of material as a valuable contribution are Beaumont's careful observations through the gastric fistula of Alexis St. Martin. Beaumont's work has recently been confirmed by Hofmeister and Schütz, who, with Rossbach, Hirsch, Openchowski, and others, have presented during the last twelve years much new and interesting information. Since, however, it will conduce to clearness to set forth the results of these investigations in connection with my own work, their consideration will be deferred until later.

It will then appear that these later investigations, like the earlier researches, disagree as to the details of the stomach movements. Such differences in results are the proper outcome of the abnormal conditions under which the studies have been conducted. Obviously, in order to see the natural movements of the stomach, the organ should be observed in its natural state, and not after it has been disturbed by removal from the abdomen, or by the adhesions and losses of substance incident to gastric fistulas.

As a means of watching the gastric motor activities under normal circumstances, Dr. H. P. Bowditch, in the autumn of 1896, suggested the use of the Röntgen rays. The present paper is the result of the work thus far completed. The kind assistance and stimulating counsel of Dr. Bowditch throughout the investigation are gratefully acknowledged.

THE ANATOMY OF THE STOMACH AND ITS RELATIONS TO THE SHADOW

It must be constantly borne in mind that the shadows described in this research are cast by the gastric contents, not by the stomach itself. Therefore the movements of the organ are not seen directly, but are indicated by their effect on the contained food. Variations in the length and breadth of the stomach can be inferred from changes in the outline of the shadow, but variations in the front-to-back diameter of the organ must be judged from changes in the intensity of the shadow.

The form of the active stomach soon after food has been taken is shown in outline in Figure 1. Since the several parts of the stomach are to be mentioned frequently, it will be well to recall them here in their relations to the outline. The larger, cardiac part of the organ lies to the left of a line through _w x_. Into it the œsophagus opens through the cardiac sphincter, or cardia, at _c_. The pyloric part, which includes all of the stomach situated at the right of a line _w x_, is closed by the pylorus at _p_. This part has two divisions: the antrum at the right of the line _y z_, and the preantral part of the pyloric portion, or middle region of the stomach, between the lines _w x_ and _y z_. The lesser curvature corresponds approximately to the anterior border of the shadow _c w p_; the greater curvature to the more extensive sweep, _c p_, along the posterior border.

[Illustration: FIGURE 1.]

The wall of the cat's stomach consists of three coats, but as this paper deals only with the functions of the muscular coat, that alone will be described. The gastric muscular fibres are disposed in three sets: an outer longitudinal layer, a middle circular layer, and a set of inner oblique fibres. The longitudinal fibres continue those of the œsophagus, and, radiating over the cardiac end, become more marked along the curvatures than on the front and back surfaces. Over the antrum they lie in a thick, uniform layer. The circular fibres form a complete investment, and are arranged in rings at right angles to the curved axis of the stomach. Towards the pyloric end they become denser and stronger, and at the pylorus form a thick bundle, the pyloric sphincter. Separating the antrum from the rest of the stomach, at _y z_, is a special thickening of the circular fibres, called by the early writers the "transverse band," and described by Hofmeister and Schütz as the "sphincter antri pylorici." The oblique fibres start from the left of the cardiac orifice and pass as two strong bands along the anterior part of the dorsal and ventral surfaces, giving off fine fasciculi to the circular musculature; towards the antrum they gradually disappear.

The musculature of the stomach consists of smooth muscle fibres, the chief physiological characteristics of which are slowness of contraction, rhythmic alternation of contraction and relaxation, and a very great tonicity, or power of prolonged contraction. The action of these muscles in the process of gastric digestion is now to be considered.

THE NORMAL MOVEMENTS OF THE STOMACH

Since the time of Haller the chief contributors to the knowledge of the mechanics of the stomach have been Beaumont, Hofmeister and Schütz, and Rossbach.

Beaumont's famous investigations on Alexis St. Martin are recorded in almost all general works on physiology. Through a gastric fistula he introduced a thermometer-tube and observed how it was affected by the motions of the stomach. His conclusions are as follows: "The circular or transverse muscles contract progressively from left to right. When the impulse arrives at the _transverse band_, this is excited to a more forcible contraction, and closing upon the alimentary matter and fluids contained in the pyloric end, prevents their regurgitation. The muscles of the pyloric end, now contracting upon the contents detained there, separate and expel some portion of the chyme.... After the contractile impulse is carried to the pyloric extremity, the circular band and all the transverse muscles become relaxed, and a contraction commences in a reversed direction, from right to left, and carries the contents again to the splenic extremity to undergo similar revolutions."

In close accord with Beaumont's description of the activities of the human stomach are the records of the investigations on the stomach of dogs by Hofmeister and Schütz. They removed the stomach from the body and placed it in a moist chamber, kept at body-heat and covered with glass. Under such conditions the organ remained active for from sixty to ninety minutes. A typical movement is described by these observers as composed of two phases. In the first phase a constriction of the circular fibres, deeper on the greater curvature, starts a few centimetres from the cardia and passes towards the pylorus. As the constriction proceeds it increases in strength until a maximum is reached about two centimetres in front of the antrum. This annular contraction, called by Hofmeister and Schütz the "preantral constriction," closes the first phase. Immediately thereafter the strong sphincter antri pylorici, or transverse band, contracts. Now, while the preantral constriction is relaxing, the sphincter antri pylorici tightens still more, and the antrum is shut off from the rest of the stomach. As soon as this has occurred a general contraction of the muscles of the antrum follows. Relaxation begins at the sphincter antri pylorici and progresses slowly towards the pylorus; it is sometimes accompanied by an antiperistaltic movement.

Although Rossbach also used dogs, his results vary considerably from those of Hofmeister and Schütz. This discrepancy is possibly accounted for by a difference in method, for Rossbach left the stomach in the body. The dogs were treated with morphia and curare, and the abdomen was then widely opened, so that the movements could be clearly seen. When the stomach was full Rossbach saw deep constrictions begin near the middle and pass in waves to the pylorus. At first these movements were weak; later, however, they became more vigorous. The fundus remained in tonic contraction about its contents and took no part in the peristalsis.

Before attempting to explain the difference in the records of these observers I shall give an account of what may be seen in a cat by use of bismuth subnitrate and the Röntgen rays.

1. _Movements of the pyloric part._--Within five minutes after a cat has finished a meal of bread, there is visible near the duodenal end of the antrum a slight annular contraction which moves peristaltically to the pylorus; this is followed by several waves recurring at regular intervals. Two or three minutes after the first movement is seen very slight constrictions appear near the middle of the stomach, and pressing deeper into the greater curvature, course slowly towards the pyloric end. As new regions enter into constriction, the fibres just previously contracted become relaxed, so that there is a true moving wave, with a trough between two crests. When a wave swings round the bend in the pyloric part the indentation made by it deepens; and as digestion goes on the antrum elongates and the constrictions running over it grow stronger, but until the stomach is nearly empty they do not entirely divide the cavity. After the antrum has lengthened, a wave takes about thirty-six seconds to move from the middle of the stomach to the pylorus. At all periods of digestion the waves recur at intervals of almost exactly ten seconds. So regular is this rhythm that many times I have been able to determine within two or three seconds when a minute had elapsed simply by counting six similar phases of the undulations as they passed a given point. It results from this rhythm that when one wave is just beginning several others are already running in order before it. Between the rings of constriction the stomach is bulged out, as shown in the various outlines in Figures 2, 3, 4, and 5. The number of waves during a single period of digestion is larger than might possibly at first be supposed. In a cat that finished eating fifteen grams of bread at 10.52 A.M., the waves were running regularly at 11.00 o'clock. The stomach was not free from food until 6.12 P.M. During that time the cat was fastened to the holder at intervals of half an hour, and the waves were always observed following one another in slow and monotonous succession. At the rate of three hundred and sixty an hour, approximately two thousand six hundred waves passed over the antrum during that single digestive period.

From the above review it will be manifest that my observations of the movements of the pyloric part agree closely with those of Rossbach, but differ considerably from the harmonious results of the work of Beaumont, and Hofmeister and Schütz. Beaumont's methods, however, may be justly criticised on the ground that the thermometer-tube which he held in the stomach was wholly unlike food and very liable to bring about unwonted contractions in so sensitive an organ as the stomach. Further, the movements observed by Hofmeister and Schütz, as Ewald has pointed out, may easily have resulted from the abnormal stimulus due to lack of

blood--a potent cause of peristalsis. And it will be shown later that the accounts given by these investigators describe very well the actions of the stomach when stimulated by an unusual irritant. In this connection it may be added that since the publication of the preliminary notice of my work, Roux and Balthazard, using the Röntgen rays, have published the results of observations on the stomachs of the dog and man similar to those thus far described in this paper.

The fact that my observations and those of Roux and Balthazard were conducted under normal conditions, and that the conditions of Rossbach's experiments were more nearly normal than those of the other observers mentioned, warrants the conclusion that the pyloric part has a more important function than that of merely expelling the contents of the stomach into the intestines. After summarising the description given by Hofmeister and Schütz, Ewald, for _a priori_ reasons, declares: "I cannot accept this view. The plain fact that the pyloric portion secretes a strongly digesting fluid containing pepsin and hydrochloric acid proves it to be an important part for the peptonising function of the stomach." The account of the remarkable manner in which the pyloric portion performs this function must be deferred until the movements of other parts of the stomach have been considered.

2. _Movements of the pyloric sphincter._--Rossbach mars his otherwise careful work by declaring that the pylorus is tightly closed during the whole digestive period of from four to eight hours, and that then the sphincter relaxes and the peristaltic waves empty the stomach. That this is not the normal action of the sphincter has been shown by several observers. Hirsch watched dogs with duodenal fistulas and saw food come from the stomach at intervals of one-fourth of a minute to several minutes. Roux and Balthazard maintain that in dogs food enters the duodenum at the completion of each wave of constriction. Observations on the cat, however, do not support their view, but agree rather with the statement of Hirsch.

In cats fed with bread mixed with subnitrate of bismuth, ten or fifteen minutes elapse after the first constriction in the antrum before any food can be seen in the duodenum. When food does appear it is spurted through the pylorus and shoots along the intestine for two or three centimetres. Not every constriction-wave forces food from the antrum. On one occasion, about an hour after the movements began, three consecutive waves were seen, each of which squirted food into the duodenum. The pylorus remained closed against the next eight waves, opened for the ninth, but closed once more against the tenth and eleventh. For each of the four succeeding waves the sphincter relaxed, but blocked the food brought by three constrictions that followed; and in this irregular way the food continued passing from the stomach. Near the end of gastric digestion, when the constrictions are very deep, it may be that the pylorus opens for every wave.

When a hard bit of food reaches the pylorus, the sphincter closes tightly and remains closed longer than when the food is soft. This action of the sphincter was shown by giving with the regular food of the cat a dry, hard pellet of equal parts of starch paste and bismuth subnitrate about the size of a pea. The food itself contained merely enough bismuth to throw a dim shadow, near the centre of which the pellet could be clearly seen as a dark object. The continual passing of the contraction-waves finally brought the little ball to the pylorus. When it arrived there, five grams of bismuth subnitrate were introduced into the stomach through a tube in the œsophagus. This was done in order that the food passing into the intestines after the ball came to the pylorus might be distinguished from that which had gone on before. By kneading the stomach the bismuth was distributed, as shown by the uniformly black shadow. The pellet could still be seen near the end of the antrum when the constrictions passed over it. Now, although the waves continued to run regularly, the very black food did not gather in the intestines in sufficient amount to be recognised until forty-two minutes after it had been introduced. And when, finally, the food did show itself in the intestines, its shadow contrasted strongly with that of the food which had already passed on. The slowness of the expulsion is not to be regarded as wholly due to the hard mass. No doubt the kneading of the stomach mixed the contents of different parts of the organ and brought to the pylorus food not yet sufficiently digested to be passed by that selective sphincter. But this does not explain the whole delay. Food similar to that given here, except that it contained no hard particles, has usually been seen as small masses in the intestines within fifteen minutes after being swallowed. A part of the delay was evidently, therefore, caused by the hard pellet. Further evidence on this point was secured when, on one occasion, the sphincter was seen to open only seven times in twenty minutes following the arrival of a hard particle of food at the pylorus. The conclusion may therefore be drawn that hard morsels keep the pylorus closed and hinder the passage of the food into the duodenum.

3. _Activity of the cardiac portion._--The part played by the fundus apparently has not hitherto been properly appreciated. It has been regarded as the place for peptic digestion, or as a passive reservoir for food; but it is in fact a most interestingly active reservoir.

[Illustration: FIGURE 2.]

[Illustration: FIGURE 3.]

[Illustration: FIGURE 4.]

[Illustration: FIGURE 5.--Figures 2, 3, 4, and 5 present outlines of the shadow of the contents of the stomach cast on a fluorescent screen by the Röntgen rays. The drawings were made by tracing the outline of the shadow on tissue paper laid upon the fluorescent surface, and are about one-half the actual size. They show the change in the appearance of the stomach at intervals for half an hour, from the time of eating until the stomach is nearly empty.]

The action of the cardiac portion will be best understood by comparing the appearances the stomach presents at various stages in a digestive period. In order to show these stages I carefully made a set of three tracings of the outlines of the stomach as soon as possible after a cat had finished eating, and another set of three every half hour thereafter, until the contents had disappeared (Figs. 2, 3, 4, and 5). These tracings were made by placing white tissue paper over the fluorescent screen, and drawing with a thick lead pencil, easily seen, as much of the boundary of the stomach as I could at the end of each expiration. Between the times for making the drawings the cat was allowed to rest quietly on a mat, but care was taken to lay her in the same position on the holder for every drawing. The drawings of each set were afterwards fastened over one another, so that the lines coincided as closely as possible. Another piece of tissue paper was then put over these, and all four sheets were laid on an illuminated pane of glass. It was thus easy to get a composite tracing which, considering the movement imparted to the stomach by respiration, and the dimness of the shadows in the later stages of digestion, probably represents more exactly than any single drawing the outline of the stomach for each successive period.

A comparison of these drawings shows that as digestion proceeds the antrum appears gradually to elongate and acquire a greater capacity, and that the constrictions make deeper indentations in it. But when the fundus has lost most of its contents, the longitudinal and circular fibres of the antrum contract to make it again shorter and smaller. Its change of form, however, compared with the rest of the stomach, is slight.

The first region to decrease markedly in size is the preantral part of the pyloric portion. The peristaltic undulations, caused by the circular fibres, start at the beginning of this portion, and gradually, by their rhythmic recurrence, press some of the contents into the antrum. As the process continues, the smooth muscle fibres with their remarkable tonicity contract closely about the food that remains, so that the middle region comes to have the shape of a tube (Figs. 3 and 4--1.30 P.M. to 2.30 P.M.), with the rounded fundus at one end and the active antrum at the other. Along the tube very shallow constrictions may be seen following one another to the pylorus.

At this juncture the longitudinal fibres which cover the fundus like radiating fingers, and the circular and oblique fibres reaching in all directions about this spherical region, begin to contract. Thus the contents of the fundus are squeezed into the tubular portion. This process, accompanied by a slight shortening of the tube, goes on until the shadow cast by the fundus is almost wholly obliterated (Fig. 5--5.30 P.M.).

The waves of constriction moving along the tubular portion press the food onward as fast as they receive it from the contracting fundus, and when the fundus is at last emptied they sweep the contents of the tube into the antrum (Fig. 5--5.00 P.M. to 6.00 P.M.). Here the operation is continued by the deeper constrictions till, finally (in this instance at 6.12 P.M.), with the exception of a slight trace of food in the fundus, nothing is to be seen in the stomach at all.

The food in the fundus may possibly be slightly affected by the to-and-fro movements of the diaphragm in respiration. With normal breathing the upper border of the cardiac portion swings through about one centimetre; with dyspnœa, or deep breathing, through one and a half or two centimetres. Since the lower border does not move so much, the contents are gently pressed, and then released from pressure, at each respiration. The pyloric portion is moved very little by the diaphragm, the oscillation being less than a half centimetre.

Moritz has pointed out the value of an organ like the stomach for holding the bulk of the food and serving it out a little at a time, so that the intestines may not become congested during their digestive and absorptive processes. All of the advantages supposed to be thus secured to the intestines may be claimed also for the stomach itself. For the preceding description indicates, and experiments to be described later prove, that the stomach is composed of two physiologically distinct portions: the busy antrum, over which during digestion constriction-waves are running in continuous rhythm; and the cardiac part, which is an active reservoir, pressing out its contents a little at a time as the antral mechanism is ready to receive them.

THE MOVEMENTS OF THE STOMACH IN VOMITING

The appearance of the stomach during vomiting has been studied particularly by Openchowski. He says that when an emetic is given there follows a quivering of the stomach-wall, which, beginning near the pylorus, shows itself later in the antral and middle regions of the stomach. The quivering afterwards passes into a contraction, most strongly marked in the antral part, since the peristaltic waves running down to the antrum from above are continually growing deeper. At the same time the fundus expands spherically. The increased contraction in the pyloric part drives the contents towards the more dilated portion, and thence they are forced into the œsophagus by abdominal pressure.

The same phenomena occur when a cat is given apomorphine hypodermatically. First the upper circular muscles relax and become so flaccid that the slightest movement of the abdomen changes the form of the fundus. Then there are apparently irregular twitchings of the fundus wall. Soon a deep constriction starts about three centimetres below the cardia and, growing in strength, moves towards the pylorus. When it reaches the transverse band the constriction tightens and holds fast, while a wave of contraction sweeps over the antrum. Another similar constriction follows. In the interval the transverse band relaxes slightly, but tightens again when the second wave reaches it. Perhaps a dozen such waves pass; then a firm contraction at the beginning of the antrum completely divides the gastric cavity into two parts. This same division of the stomach into two parts at the transverse band is to be seen when mustard is given. Now, although the waves are still running over the antrum, the whole preantral part of the stomach is fully relaxed. A flattening of the diaphragm and a quick jerk of the abdominal muscles, accompanied by the opening of the cardia, now force the contents of the fundus into the œsophagus. As the spasmodic contractions of the abdominal muscles are repeated, the gastric wall again tightens around the contained food. Antiperistalsis I have seen only once; then, while the cat was retching, a constriction started at the pylorus and ran back, over the antrum, completely obliterating the antral cavity.

It will be recalled that the principal difference between the movements of the stomach and their effects as described by Beaumont, and Hofmeister and Schütz on the one hand, and Rossbach, Roux and Balthazard, and myself on the other hand, is that the former observed constrictions completely dividing the stomach at the transverse band, and the antrum then squeezing its contents into the intestines; whereas the latter have seen the constrictions moving forward as narrowing rings, but not separating the gastric cavity into two parts.

With the exception of peristalsis in the antrum, the gastric movements at the beginning of emesis are almost exactly the same as those Beaumont, and Hofmeister and Schütz, declare to be the normal contractions of the stomach. Their observations were made, however, when the organ was subjected to unnatural stimulation. In the excised stomach, observed by Hofmeister and Schütz, not only were all nervous connections severed, but likewise all flow of blood to the organ was entirely stopped, and the cutting off of the blood supply is regarded as one of the most powerful predisposing causes of peristaltic action. The thermometer-tube used by Beaumont was an irritant to the stomach, as he himself admits. “If the bulb of the thermometer,” he writes, “be suffered to be drawn down to the pyloric extremity, and retained there for a short time, or if the experiments be repeated too frequently, it causes severe distress and a sensation like cramp, or spasm, which ceases on withdrawing the tube, but leaves a sense of soreness and tenderness at the pit of the stomach.” Moritz also noticed that a rubber sound introduced into the human stomach proved to be a source of irritation. It seems reasonable to suppose, therefore, that these observers did not see the normal movements, but the actions resulting from abnormal irritation.

THE EFFECT OF THE MOVEMENTS OF THE STOMACH ON THE FOOD

In my first observations on the active stomach a bulging of the stomach-wall was to be seen in front of the passing waves. But as food did not immediately appear in the intestine, and as, after the pylorus relaxed, the gastric contents did not diminish rapidly enough to allow the supposition that all of the food squeezed forward by the waves was immediately forced through the pylorus, it was assumed that a part, at least, of the food under pressure was forced back towards the cardia through the constriction-ring. This inference was stated in the preliminary notice of my work. Roux and Balthazard also observed the passage of the undulations over the pyloric part, but state merely that the function of the constrictions is the propulsion of food into the intestine, without mentioning what must be regarded as a very important function; namely, the mixing effect of the waves.

Most writers have agreed that the result of the active and passive movements of the stomach is to force the contents hither and thither, thus mixing them and the gastric juice together. Two observers, Beaumont and Brinton, have attempted to explain the manner of the mixing. Beaumont, after noting how the thermometer-tube, used by him to indicate the gastric motions, was affected, describes the circulation of the food as follows: “The bolus as it enters the cardia turns to the left, passes the aperture, descends

into the splenic extremity, and follows the great curvature towards the pyloric end. It then returns, in the course of the small curvature, makes its appearance again at the aperture, in its descent into the great curvature, to perform similar revolutions." Brinton bases his theory of the circulation of the food on an analogy between the movement of a constriction over the stomach and the passage of a septum with a central perforation along the interior of a cylinder full of liquid. The result in both cases, he declares, must be a peripheral current of advance, and a central current of return. Thus in the stomach there would be peripheral currents from the cardia along the walls of the stomach to the pylorus, where they would unite and run as an axial current back to the cardia.

Certain _a priori_ objections may be urged against each of these conclusions. In the first place Beaumont's observations were made on a subject having a gastric fistula, and the adhesions between the stomach and the abdominal wall would prevent the fundus from acting quite normally in relation to its contents. Beaumont's conclusions, furthermore, are based on the movements of a thermometer-tube introduced through the fistula, and on the recognition of particles of food which he had seen before as they passed the fistulous opening: the first method, as has been shown, made the conditions in the stomach more abnormal than they were previously; the second gave uncertain knowledge of the course of the food when out of the observer's sight. Brinton's hypothesis states the probable movements of fluid contents acted on by a passing constriction. But it may be objected that the conditions assumed by him do not exist in all parts of the stomach. For not only is there no peristalsis visible in the fundus, but with the usual food the fundus contents are not liquid. Moreover, the constrictions at the beginning of the pyloric portion are very slight and move slowly. The food in front of them is, accordingly, not under much greater pressure than the food behind them. The axial current which might result, therefore, could not be strong enough to go far into the cardiac portion.

It is easily possible to test experimentally the validity of these two theories by watching the action of pieces of food which throw a black shadow in a dimly outlined stomach. For this purpose little paste pellets of bismuth subnitrate, with starch enough to keep the form, were given with the customary meal. These pellets, it was found, did not break up in the stomach during the gastric digestion of soft bread. Several times I have been fortunate in getting two of the little balls in the axis of the stomach and about a centimetre apart. As the constriction-wave approached them, both moved forward, but not so rapidly as the wave. Now when the constriction overtook the first ball, the ball moved backward through the constricted ring, in the direction of least resistance. The wave then overtook the second ball, and it also passed backward to join its fellow. At the approach of the next wave they were both pushed forward once more, only to be again forced backward, one at a time, through the narrow orifice. As the waves recurred in their persistent rhythm, the balls were seen to be making progress--an oscillating progress--towards the pylorus; for they went forward each time a little farther than they retreated. This to-and-fro movement of the pellets was much more marked in the antrum, where the waves were deep, than in the middle region. On different occasions from nine to twelve minutes have elapsed while the balls were passing from where the waves first affected them to the pylorus; which means that on the way they were moved back and forth by more than a half hundred constrictions.

If the pylorus does not relax, it is evident that a wave approaching it pushes the food into a blind, elastic pouch, the only exit from which is through the advancing constricted ring. The constrictions are deeper near the end of the antrum, and the rings are small; consequently, the food is squirted back through them with considerable violence. As has been noted, the pylorus opens less frequently for a while after a solid piece of food comes to it. In such a case the slow driving waves squeeze the hard morsel and the soft food about it up to the sphincter, only to have the whole mass shoot back, sometimes half-way along the antrum. Over and over again the process is repeated till the sphincter at last opens and allows the more fluid parts to pass. Hofmeister and Schütz, and Moritz have disclaimed any selective action of the pylorus, and declare that solids are driven from the pylorus to the fundus by antiperistalsis. The action of the pylorus which I have seen, however, is more like that described by the earlier investigators; for during digestion there was no antiperistalsis, and the sphincter, separating the fluids from the solids, caused the solids to remain and undergo a tireless rubbing. Frequently, when several of these balls have been given at the same time, they have all been seen in the antrum after the stomach was otherwise empty. Here they remain to be softened in time by the juices, or to be forced through the pylorus later, for solids do pass into the intestine. Thus when the teeth neglect their work the stomach attempts to perform their function; the relative inefficiency of the gastric method of grinding and its interference with the normal gastric activities point an obvious hygienic moral.

During the process of digestion the food in the cardiac portion gives no sign of currents. Balls which lie in the fundus immediately after the food is ingested keep their relative positions until the cardiac portion begins to contract, and then move very slowly towards the antrum. Moreover, the food in the fundus of a cat has the same mushy appearance when examined after gastric peristalsis had been active for an hour and a half that it had when ingested. The contents of the antrum, on the other hand, look quite different and have the consistency of thick soup. The inactivity of the food in the fundus can also be proved by feeding first

five grams of bread and bismuth, then five grams without bismuth, and finally five grams again with bismuth in it. The stomach contents are thus arranged in two dark layers along the curvatures, with a light layer between. Tracings made on tissue paper show that ten minutes after peristalsis commenced the stratification had entirely disappeared in the pyloric part, but that an hour and twenty minutes thereafter the layers were still clearly visible in the cardiac region.

The value of the circulation of the food, as described by Beaumont and Brinton, lay in the supposition that the contents of the stomach were thus brought near to the secreting gastric wall, and that the gastric juice could thus more readily exert its action. Although my observations do not support their theories of mixing currents running throughout the stomach, they still show that the pyloric portion is an admirable device for bringing all of the food under the influence of the glandular secretions of that region. For, when a constriction occurs, the secreting surface enclosed by the ring is brought close around the food lying within the ring in the axis of the stomach. As this constriction passes on, fresh areas of glandular tissue are continuously pressed in around the narrow orifice. And also, as the constriction passes on, a thin stream of gastric contents is continuously forced back through the orifice, and thus past the mouths of the glands. The result of this ingenious mechanism is that every part of the secreting surface of the pyloric portion is brought near to every bit of food, before the latter leaves the stomach, a half hundred times or more, as evidence by the moving ball.

SALIVARY DIGESTION IN THE STOMACH

The absence of movement in the fundus would seem to give the food during its stay there little opportunity to become mixed with the gastric juices, and thus to undergo peptic digestion. The truth of this supposition can easily be proved experimentally by feeding a slightly alkaline meal, and later testing the chemical reaction of the contents of various parts of the stomach. A cat which had been without food for fifteen hours was given eighteen grams of mushy bread made slightly alkaline with sodium carbonate. One hour and a half after the cat had finished eating she was killed, and the stomach laid bare by opening the abdomen. A very small hole was then made through the wall in the fundus region, and another similar hole was made into the antrum. By means of a glass pipette food was extracted first from the periphery of the fundus; this food was slightly acid. The cleaned pipette was then introduced two and a half centimetres into the fundus contents, and the food thus extracted gave the original alkaline reaction. Specimens of the liquid contents of the antral and middle regions, taken from various depths, were all strongly acid. A dog killed an hour and three-quarters after eating showed similar differences between the reactions of the food in the fundus and the food in the pyloric portion. So, as a matter of fact, the food does not become acid at a uniform rate in all parts of the stomach, as would be the case if Beaumont's and Brinton's theories of mixing currents were true. Moreover, if the facts accorded with their notions, the saliva, which ceases to act in the presence of more than 0.003 per cent free hydrochloric acid, and is destroyed when the percentage of acid proteids is large, would manifestly have its service as a ferment limited to the relatively short time during which the stomach contents, in the process of thorough mixing, were reaching that degree of acidity. There is, however, no movement of food in the fundus, and the alkaline food received from the œsophagus remains alkaline in this region for a considerable period. The nutriment, therefore, if well chewed and thus mixed with saliva, can undergo salivary digestion in the fundus for a considerable period without interference by the acid gastric juice.[32]

From all these observations the conclusion must be that the fundus acts as a reservoir for the food, in which the digestion of sugars and starches may take place; and that the pyloric portion with its simple but marvellous peristaltic mechanism, by a single process, triturates the food, brings it near to the active glands, stirs it thoroughly with their secretions, and expels the products into the intestines.

THE INHIBITION OF STOMACH MOVEMENTS DURING EMOTION

Early in the research a marked unlikeness was noticed in the action of the stomachs of male and female cats. The peristalsis seen with only a few exceptions in female cats failed to appear in most of the males, although both had received exactly the same treatment. Along with this difference was a very striking difference in behaviour when bound to the holder; the females would lie quiet, mewing occasionally, but purring as soon as they were gently stroked. The males, on the contrary, would fly into a violent rage, struggle to be loose from their fastenings, bite at everything near their heads, cry loudly, and resist all attempts to quiet them. On account of this difference only female cats were used for some time, and the significance at first attributed to the action of the males was almost forgotten when the following incident recalled it and suggested that the excitement caused the suspension of the stomach movements. On October 23, 1897, a male cat was fed at 12.00, but was not placed on the holder till ninety minutes later. The waves were passing at the rate of six a minute. The cat fell into a rage and the waves suddenly stopped.

A few days later an observation on a female with kittens explained the absence of gastric movements in the males. While the peristaltic undulations were coursing regularly over the cat's stomach, she suddenly changed from her peaceful sleepiness, began to breathe quickly, and struggled to get loose. As soon as the change took place, the movements in the stomach entirely disappeared; the pyloric portion relaxed and presented a smooth, rounded outline. I continued observing, and stroked the cat reassuringly. In a moment she became quiet and began to purr. As soon as this happened the movements commenced again in the stomach; first a few constrictions were visible near the end of the antrum, then a few near the sharp bend in the lesser curvature, and finally the waves were running normally from their habitual starting-place. By holding the cat's mouth closed between the thumb and last three fingers, and covering her nostrils with the index finger, she could be kept from breathing. At the first sign of discomfort the fingers were removed. This experiment was repeated a great many times on different cats, and invariably the evidence of distress was accompanied by a total suspension of the motor activities of the stomach and a relaxation of the antral fibres.

No amount of kneading or compression of the abdomen with the fingers, short of making the cat angry, would cause the waves to stop; so that the cat's movements, in themselves, were not the source of the inhibition. And since expressions of strong feeling on the part of the animal always accompanied cessation of the constriction-waves, the inhibition was probably due to nervous influence. It has long been common knowledge that violent emotions interfere with the digestive process, but that the gastric motor activities should manifest such extreme sensitiveness to nervous conditions is surprising.

SUMMARY

1. By mixing a harmless powder, subnitrate of bismuth, with the food, the movements of the stomach can be seen by means of the Röntgen rays.

2. The stomach consists of two physiologically distinct parts: the pyloric part and the fundus. Over the pyloric part, while food is present, constriction-waves are seen continually coursing towards the pylorus; the fundus is an active reservoir for the food and squeezes out its contents gradually into the pyloric part.

3. The stomach is emptied by the formation, between the fundus and the antrum, of a tube along which constrictions pass. The contents of the fundus are pressed into the tube and the tube and antrum slowly cleared of food by the waves of constriction.

4. The food in the pyloric portion is first pushed forward by the running wave, and then by pressure of the stomach-wall is returned through the ring of constriction; thus the food is thoroughly mixed with gastric juice, and is forced by an oscillating progress to the pylorus.

5. The food in the fundus is not moved by peristalsis, and consequently it is not mixed with the gastric juice; salivary digestion can therefore be carried on in this region for a considerable period without being stopped by the acid gastric juice.

6. The pylorus does not open at the approach of every wave, but only at irregular intervals. The arrival of a hard morsel causes the sphincter to open less frequently than normally, thus materially interfering with the passage of the already liquefied food.

7. Solid food remains in the antrum to be rubbed by the constrictions until triturated, or to be softened by the gastric juice, or later it may be forced into the intestine in the solid state.

8. The constriction-waves have, therefore, three functions: the mixing, trituration, and expulsion of the food.

9. At the beginning of vomiting, the gastric cavity is separated into two parts by a constriction at the entrance to the antrum; the cardiac portion is relaxed, and the spasmodic contractions of the abdominal muscles force the food through the opened cardia into the œsophagus.

10. The stomach movements are inhibited whenever the cat shows signs of anxiety, rage, or distress.

THE MOVEMENTS OF THE INTESTINES STUDIED BY MEANS OF THE RÖNTGEN RAYS[33]

BY W. B. CANNON

From the Laboratory of Physiology in the Harvard Medical School

Extracts from _American Journal of Physiology_, 1902

INTRODUCTION

The investigation of intestinal movements has been beset by the same difficulties that characterised the investigation of the gastric mechanism. Pathological subjects or animals subjected to the disturbing action of drugs and anæsthetics and of serious operations have been the only sources of our knowledge. A considerable difference of opinion as to the nature of the normal movements in the intestines has resulted from observations made under these necessary abnormal conditions. The slowly advancing peristaltic wave and the _Pendelbewegung_, or swaying movement, described by Ludwig, have been regarded as true physiological processes. Concerning antiperistalsis and the swiftly running vermicular contraction, observers are not so nearly in agreement. The activity of the large intestine has been described as simply peristalsis of a slower rate than that seen in the small intestine.

The best known of the intestinal movements is the normal peristaltic wave. This wave is slow, having a rate of about two centimetres per minute, is regular, and by most observers is said to move always in one direction. The progress of the contraction, as suggested by Nothnagel's experiments, and as clearly stated by Mall and by Bayliss and Starling, is dependent upon a local reflex. According to Mall, when an object stimulates the mucosa there occurs above the point of stimulation a constriction which forces the object downward; and as it moves downward new regions immediately above the mass are by this reflex brought into constriction, and thus the wave and its stimulus advance together. "At the same time," Mall states, "a sucking force, due to active dilatation below the body, may have a tendency to drag it down." In what manner an active dilatation of the intestinal wall may occur so as to produce a "sucking force" he does not make wholly clear. Bayliss and Starling, in describing normal peristalsis in the intestine, state that the contractions above the bolus increase until there is a strong tonic constriction. This passes the bolus onward, and as it advances the ring of constriction follows it. While the bolus is passing down, the gut above it is traversed by waves running as far as the constricted ring. These observers state the law of intestinal peristalsis thus: "Local stimulation of the gut produces excitation above and inhibition below the excited spot."

The pendulum movements are characterised by a gentle swaying motion of the coils, and are accompanied by rhythmical contractions of the intestinal wall. They continue with undiminished force after paralysis of the local nervous mechanism by nicotine or cocaine; they have been called, therefore, myogenic or myodromic contractions. Observers have described them variously as shortenings and narrowings of the gut, rhythmically repeated at nearly the same intestinal circumference; as alternating to-and-fro movements of the long axis without changes in the lumen; as local or extensive periodic contractions and relaxations mainly of the circular musculature; and as waves involving both muscular coats of the intestine, and travelling normally from above downward at a rapid rate (2 to 5 cm. per second). They have been seen in the dog, and in the rabbit and cat. In the cat Bayliss and Starling noticed that when the lumen of the gut was distended by a rubber balloon, there appeared rhythmical contractions, which nearly always were most marked at about the middle of the balloon; _i. e._, the region of greatest tension. This form of constriction, which, as my observation shows, is an indication of the manner in which the rhythmical contraction acts in the cat's intestine, Bayliss and Starling seem to have regarded with slight attention, since it did not accord with the law of peristalsis.

The swift vermicular wave may pass the whole length of the intestine in about a minute. It is often seen just after death, as well as in pathological states such as intestinal anæmia or hyperæmia, and when the bowel contains gases and organic acids from decomposing food. Starling is inclined to regard this type of intestinal activity as an exaggeration of the rhythmic type; Mall, on the other hand, places it in a class by itself, and declares that its service is to rid the intestine rapidly of irritating substances. Nothnagel, who designates this form of movement with the term _Rollbewegung_, thinks it is transitional between a physiological and a pathological activity.

The existence of antiperistalsis has been so much questioned that it will be considered in a special section of this paper, where my observations may be conveniently introduced.

The common understanding of the manner in which food passes through the intestinal canal is that the chyme ejected from the stomach is pressed downward by a peristalsis, which passes slowly over a part or all of the small intestine. The peristaltic waves of the colon are supposed to constitute an independent group, similar to those of the small intestine, but weaker and slower. Movements of the food other than the uninterrupted advance have been mentioned by some observers. Starling states that the effect of the pendulum movement is to mix the contents of the intestine and bring them into intimate contact with the mucous membrane. Grützner writes that he has been brought "by strange and peculiar observations" to believe that the fluid contents of the small intestine move irregularly forward, then forward and back, then perhaps remain quiet for some time, only to pass backward for a long distance, and finally to move forward steadily to the end. In this manner the food is mixed and brought into contact with the absorbing walls. The to-and-fro shiftings of the food Grützner ascribed to advancing and retrograde contractions of the intestinal

musculature, and he argued that even circular constrictions must force the liquid contents away in both directions. To support his contention, Grützner introduced mercury into the intestine and observed it with the Röntgen rays. After noting a backward and forward movement of the mercury he dismissed the method, saying, “Many a flash must come from the Röntgen tube before the _normal_ movement of the intestinal contents is made entirely clear by this method.”

The following account is a summary of many repeated observations on different animals, and is a contribution to a clear understanding of the normal movements of the intestines and their contents.

THE MOVEMENTS OF THE SMALL INTESTINE

When the food has been distributed through the intestine so as to present the appearance shown in Figure 1, a noticeable feature in most or all of the loops is the total absence of movement. If the animal remains quiet, however, only a few moments elapse before peculiar motions appear in one or another of the loops, or perhaps in several, and last for some time. These motions consist in a sudden division of one of the long, narrow masses of food into many little segments of nearly equal size; then these segments are again suddenly divided and the neighbouring halves unite to make new segments, and so on, in a manner to be more fully described. I have called this process the rhythmic segmentation of the intestinal contents. Further observation reveals peristalsis here and there, and under certain circumstances the typical swaying movements may be seen. All these phenomena are now to be considered in detail.

[Illustration: FIGURE 1.--Appearance of food in the intestines 5¾ hours after eating. This and other radiographs reduced two-thirds.]

[Illustration: FIGURE 2.--Diagram representing the process of rhythmic segmentation. Lines 1, 2, 3, 4 indicate the sequence of appearances in the loop. The dotted lines mark the regions of division. The arrows show the relation of the particles to the segments they subsequently form.]

Rhythmic segmentation of the intestinal contents.--This is by far the most common and the most interesting mechanical process to be seen in the small intestine. The nature of the process may best be understood by referring to the diagram in Figure 2. A string-like mass of food is seen lying quietly in one of the intestinal loops (line 1, Fig. 2). Suddenly an undefined activity appears in the mass, and a moment later constrictions at regular intervals along its length cut it into little ovoid pieces. The solid string is thus quickly transformed, by a simultaneous sectioning, into a series of uniform segments. A moment later each of these segments is divided into two particles, and immediately after the division neighbouring particles (as _a_ and _b_, line 2, Fig. 2) rush together, often with the rapidity of flying shuttles, and merge to form new segments (as _c_, line 3, Fig. 2). The next moment these new segments are divided, and neighbouring particles unite to make a third series, and so on. At the time of the second segmentation (line 3, Fig. 2) the end particles are left small. Observation shows that these small pieces are not redivided. The end piece at A simply varies in size with each division; at one moment it is left small, at the next moment it is full size from the addition of a part of the nearest segment, and a moment later is the small bit left after another division. The end piece at B (probably the rear of the mass) shoots away when the end mass is divided, and is swept back at each reunion to make the large end mass again, only to be shot away and swept onward with each recurrence of the constrictions. Thus the process of repeated segmentation continues, with the little particles flitting towards each other and the larger segments shifting to and fro, commonly for more than half an hour without cessation. From the beginning to the end of a period of segmentation the food is seen to have changed its position in the abdomen to only a slight extent; whether this change is a passing of the food along the loop, or a movement of the loop itself, it is impossible to tell from the shadows on the screen. The change of position, however, is much less conspicuous than the lively division and redivision which the mass suffers so many times from the busy, shifting constrictions.

From this typical form of rhythmic segmentation there are several variations. Sometimes, and especially when the mass of food is thick, the constrictions do not make complete divisions and are so far apart that the intermediate portions are relatively large. Moreover, the constrictions do not take place in the middle of each portion, but near one end; thus each portion is constricted, not into halves, but into thirds. If a little pointer is placed at the middle of a segment, when the segments are completely divided into halves, in a few seconds the pointer will be in the middle of the clear space between two segments; but in a few seconds more the first phase will return and the pointer will again be indicating a segment,--two operations intervene between similar phases. When, however, the portions are constricted into thirds, the indicator shows it, since three operations intervene between similar phases. The manner of these changes is made clearer by reference to the diagram in Figure 3. That each portion is constricted into three pieces is proved also by watching the gradual reduction of the portion at the left end of line 1 through lines 2 and 3, and also in the

gradual formation of a full-sized portion at the right end of lines 2, 3, and 4. When food undergoing this process is watched, it appears to be affected by a series of constrictions, each of which starts at one end of the mass and marches through to the other end, leaving its impress at short intervals along the length. The progression of the dotted lines from right to left in _a_, _b_, _c_, and _d_, etc., Fig. 3, gives a notion of these advancing constrictions.

Another variation of the segmentation is shown in Figure 4. In this type there are evidently divisions and subdivisions, _i.e._, one more operation between the appearance and the reappearance of the same phase than is present in the simple division of the small segments in a long string of food (Fig. 2). This form of segmentation is fairly typical for the constrictions seen in food advancing through the intestine. Sometimes the divisions occur in the middle of a long string of food and leave the ends wholly unaffected.

[Illustration: FIGURE 3.--Diagram showing the relations of the portions when they are constricted into three pieces. The dotted lines indicate regions of constriction; the arrows indicate the relationship of the pieces to the portions they subsequently form.]

A remarkable feature in the segmentation of the food is the rapidity with which the changes take place. The simplest way of estimating the rate of division is to count, not the number of times the partition of the food recurs in the same place, but the number of different sets of segments observed in a given period. Thus in Figure 4 the appearances of lines 1, 2, 3, 4, etc., would be counted, and not merely lines 1, 4, etc. Repeated observations on different animals have shown that the most common rate of division in long, thin chains of food varies between twenty-eight and thirty times in a minute; _i. e._, there is a change from one set of segments to another set every two seconds, and a return of the same phase every four seconds. In some cases the rate is as low as twenty-three times per minute. The larger masses seem to be associated with a slower segmentation; the operations indicated in Figure 3, for example, occurred from eighteen to twenty-one times in a minute, so that the same phase reappeared only once in eight or nine seconds. The segmentation frequently continues for more than half an hour; in one instance it was seen to persist with only three short periods of inactivity for two hours and twenty-two minutes. At the rate of thirty segmentations per minute it is clear that a slender string of food may commonly undergo division into small particles more than a thousand times while scarcely changing its position in the intestine.

I have seen once, in a cat only lightly etherised, the exterior of an intestine which was dividing the food as above described. An hour and a half after a meal of salmon the anæsthetic was given, the abdomen opened, and the flaps raised so as to form walls. Warm salt solution was then poured into the abdominal cavity, and the floating coils left covered with the transparent omentum. The gastric peristaltic waves were running regularly; on the intestine there were visible at various places during the period of observation regions of constriction which had the appearance shown in Figure 3, except that the rings were relatively nearer together. New rings of constriction took place on the same side of all the bulging parts at the margin of the constricted portion (_cf._ dotted lines, Fig. 3). As new rings occurred the old relaxed, but apparently with tardiness, for the contents gurgled as if forced through the narrowed lumen. The constrictions recurred irregularly and at much longer intervals than in the normal animal. The contracted rings were pale and bloodless.

The effect of the process of rhythmic segmentation proves it an admirable mechanism. The food over and over again is brought into closest contact with the intestinal walls by the swift kneading movement of the muscles. Thereby not only is the undigested food intimately mixed with the digestive juices, but the digested food is thoroughly exposed to the organs of absorption. Mall has shown that contraction of the intestinal wall has the effect of pumping the blood from the submucous venous plexus into the radicles of the superior mesenteric vein, and thus materially aids the intestinal circulation. Moreover, lacteals loaded with fat will in a few moments become empty unless the intestine is slit lengthwise, so that the muscles cannot exert compression. The rhythmic constrictions, therefore, both propel the blood in the portal circulation and act like a heart in promoting the flow of lymph in the lacteals. This single movement with its several results is an excellent example of bodily economy; the repeated constrictions, as already shown, thoroughly churn the food and digestive fluids together, and also plunge the absorbing mucosa into the very midst of the food masses: but not only are the processes of digestion and absorption favoured by these movements; they also, by compression of the veins and lacteals of the intestinal wall, serve to deport through blood and lymph channels the digested and absorbed material.

Peristalsis.[34]--The phenomena of peristalsis and segmentation are usually combined in some manner while the food passes through the small intestine. Peristalsis is observed normally in two forms: as a slow advancing of the food for a short distance in a coil, and as a rapid movement sweeping the food without pause through several turns of the gut. The latter form is frequently seen when the food is carried on from the duodenum; and it may readily be produced in other parts of the small intestine by giving an enema of soapsuds.

When a mass of food has been subjected for some time to the segmenting activity of the intestine, the separate segments, instead of being again divided, may suddenly begin to move slowly along the loop in which they lie. That this movement is not a swinging of the coil as a whole, but a peristaltic advance of separate rings of its circular musculature, is made probable by the fact that the succeeding segments follow along the same path their predecessors have taken. The advance of the little pieces may continue for seven or eight centimetres, when finally the front piece stops or meets other food. Then all the succeeding pieces are swept one by one into the accumulating mass, which at last lies stretched along the intestine, a solid string manifesting no sign of commotion.

[Illustration: FIGURE 4.--Diagram showing combined peristalsis and segmentation.]

Another form of slow peristalsis is frequently observed when the food is pushed forward, not in small divisions, but as a large lump. The relatively long string of food is first crowded into an ovoid form as the forward movement begins, and as it is collecting thus, it seems at the last to be suddenly formed into a more rounded ball, as if the mass were pulled or pushed together at the two ends. The next moment it is indented in the middle by a circular constriction (as shown in Fig. 4, line 2), which spreads it in both directions along the loop. The trailing portion (_a_) is next cut in two, and the severed part sometimes flies back over its course about a centimetre. Now the whole mass is swept together again and slightly forward as shown in line 4, Fig. 4, and the segmenting process is repeated. At stage 3, Fig. 4, a constriction sometimes appears around the middle of the advanced portion (_b_). Thus, with many halts and interruptions, the food slowly advances.

A slight variation of the movement just described is observed when the amount of food is greater and extends farther along the intestine. Under such circumstances, as the mass moves forward, constrictions appear just in front of the rear end, which separate it from the main body, and cause it to shoot backward sometimes through the distance of a centimetre. The main body meanwhile is not disturbed. No sooner has the rear section been shot away than it is swept forward again into union with the rest of the food, and the whole mass then advances until another interfering constriction repeats the process.

Rhythmic segmentation and the pendulum movement.--There is little doubt that the segmentation of the food which I have seen is due to an activity of the intestinal musculature similar to that which causes the so-called pendulum movement. This activity, as already noted, is rhythmic, and, although accounts differ, analytical methods prove that it involves both the longitudinal and the circular layers of muscle. Observations of the effect of the rhythmic contractions upon the food show that the action of the circular fibres is most prominent. It is probable, however, that the longitudinal fibres also play an important part in the process of segmentation. Examination of Figure 2 makes clear that in line 2 the regions of constriction appear between the regions of constriction in line 3; before _c_ can be formed, therefore, the constriction between _a_ and _b_ must relax. Contraction of the longitudinal fibres between two segments would help to enlarge the constricted lumen of the gut. It seems probable that, as the constrictions on either side of _c_ occur, the longitudinal fibres between them contract; almost simultaneously the constriction between _a_ and _b_ relaxes, and the two particles are thus brought swiftly together. A similar process naturally would take place for each of the shifting segments. Thus the function of the longitudinal muscles would be to contract between new rings of constriction and thereby aid in relaxing the former ring between them. During my one observation of the segmenting process, as seen on the surface of the intestine, I could not be sure that the distance between neighbouring segments was shortened as the constriction relaxed; that activity of the longitudinal fibres is present, however, is indicated by observations of Raiser on the intestines of the rabbit and the cat. Raiser observed the outer surface of the coils, and describes the normal movement as an alternate contraction and relaxation of single divisions of the longitudinal fibres; he notes that these short divisions shift. But whether they shift in alternation with the shifting circular constrictions, as seems probable, is an interesting point not yet determined.

[Illustration: FIGURE 5.--Tracing showing segmentation of chyme in the duodenum. This and other tracings reduced two-thirds.]

Bayliss and Starling state that the swaying pendulum movements are essentially due to peristaltic waves recurring in the same place and running rapidly downward. This form of the movements I have seen only once. At this time about 90 c.c. of soapy water had been injected. This procedure has the effect of exaggerating in every particular the movements of the small intestine. In this instance a broad constriction appeared about the middle of a long string of food and persisted there while it spread down the gut. As the contraction spread, the gut swayed slowly to and fro before it. Then there was a relaxation, followed by a recurrence of the constriction in the same place, a spreading of the contraction, and a swinging of the loop just as before. This phenomenon was repeated again and again, till finally the string was divided and the forward piece pushed through a tortuous course to the colon.

The course of the food in the small intestine.--Chyme is not forced from the stomach by every wave that passes over the antrum, but only at intervals. When the pylorus relaxes, the food, moved towards the pylorus under considerable pressure, is squirted along the duodenum for two centimetres or more. Careful watching of this food shows that usually it lies for some time in the curve of the duodenum until additions have been made to it from the stomach, and a long, thin string of food is formed. While it is resting in this place it is exposed to the outpouring of the bile and pancreatic juices. All at once the string becomes segmented (see Fig. 5) and the process of rhythmic segmentation continues several minutes, thoroughly mixing the intestinal digestive juices with the chyme. In this region the alternate positions of the segments are sometimes far apart, and the to-and-fro movements of the particles may be a relatively extensive and very energetic swinging. Finally the little segments unite into a single mass, or form in groups, and begin to move forward. The peristalsis here, as already mentioned, is much more rapid than the normal peristalsis elsewhere in the small intestine. The masses, once started, go flying along, turning curves, whisking hither and thither in the loops, moving swiftly and continuously forward. After passing on in this rapid manner for some distance the food is collected in thicker and longer strings, resembling the strings seen characteristically in the other loops. Towards the end of digestion the small masses shot out from the stomach, after a few segmentations, may move on in the rapid course without being accumulated in a larger mass until the swift movement ceases.

During the first stages of digestion in the cat's small intestine the food usually lies chiefly on the right side of the abdomen; during the last stages the loops on the left side contain the greater amount of food. In these loops the food remains sometimes for an hour or more with no sign of movement. All at once a mass begins to show irregular depressions and elevations along its length, and then suddenly it is divided, at first partially, later completely, into many little equal parts, and these repeatedly undergo division and reunion, division and reunion, over and over again, in the manner described above as rhythmic segmentation. After a varying length of time the activity wanes and the little segments are carried forward individually and later brought together, or join and move on as a single body, or they may reunite and lie quietly for some time without further change. Thus by a combined process of kneading and peristaltic advance the food is brought to the ileocæcal valve to enter the large intestine. Records from ten different animals show that salmon does not appear in the small intestine until an hour or an hour and a half after the food is eaten. Inasmuch as five or six hours elapse after eating before this food begins to be seen in the colon, it is evident that the chyme takes four to five hours to pass the length of the small intestine. It is interesting to note that the operations are considerably shortened if the meal has consisted of bread and milk.

THE COMPETENCE OF THE ILEOCÆCAL VALVE

The ileocæcal valve in the cat is situated three or four centimetres from the blind end of the cæcum. Its position is usually marked in shadows of the food in the colon by a slight indentation, towards which masses about to enter the colon are ordinarily directed from a point somewhat distant in the small intestine (see Fig. 6).

Regarding the competence of the ileocæcal valve many observations have been made. Grützner has reviewed the evidence bearing on the question and concludes that the valve is not competent, least of all for liquids. He declares that as soon as liquids or thin fluid masses appear in the upper part of the colon they pass in many instances into the small intestine the moment that the pressure on the colon side rises slightly. If the colon contains a solid or a thick, mushy mass, the passage towards the small intestine is scarcely possible, because every increase of pressure in the large intestine must force the two lips of the valve together and close it.

The importance of the competence of the ileocæcal valve under normal conditions cannot be appreciated until the function of the first part of the colon is considered. In order that this part of the intestinal mechanism may perform its service, the competence of the valve for the food which enters the colon from the ileum should be perfect. As a matter of fact, such is the case. Not only does the activity of the colon prove this statement, but the failure of every attempt to drive the food in the colon back through the valve into the ileum confirms the proof. Again and again I have tried, by manipulation through the abdominal wall, to press the normal contents of the colon downward with sufficient force to cause them to return to the small intestine, but without success. The valve held perfectly.

THE MOVEMENTS OF THE LARGE INTESTINE

When the large intestine is full, palpation through the abdominal wall demonstrates that the material in the lower descending colon and in the sigmoid flexure is usually composed of hard, incompressible lumps, while that in the ascending and transverse colon and the cæcum is soft, permitting the walls of the gut to be easily pushed together. The condition of the contents in these two regions

seems to indicate a rough division of the large intestine into two parts, and the mechanical activities of these two parts verify the differentiation. In the descending colon the material is very slowly advanced by rings of tonic constrictions (see Fig. 7); in the ascending and transverse colon and in the cæcum by far the most common movement is an antiperistalsis.

Antiperistalsis in the colon.--The colon of cats which have been without food for a day usually contains enough gas to make the position of the gut distinguishable with the fluorescent screen (see Fig. 1). The first food to enter the colon from the small intestine is carried by antiperistaltic waves into the cæcum (Fig. 1), and all new food as it enters is also affected by these waves. Thus the contents of the colon, instead of being driven immediately toward the rectum by slow peristalsis, as is the general opinion, are first repeatedly pushed toward the cæcum by an antiperistaltic action.

These antiperistaltic waves follow one after another like the peristaltic waves of the stomach (see Figs. 5, 6, and 10). They begin either on the more advanced portion of the food in the colon (when only a small amount is present), or at the nearest tonic constriction, which is usually at the turn between the transverse and descending colon (Figs. 7 and 8.) The waves rarely run continuously for a long time. When the colon is full, it is usually quiet. The first sign of activity is an irregular undulation of the walls, then very faint constrictions passing along the gut towards the cæcum. These constrictions may first appear only on the ascending colon. As they continue coursing over the intestine they become deeper and deeper, until there is a marked bulging between successive constrictions. When the waves have thus become more prominent, they are seen to start near the end of the transverse colon and pass without interruption to the end of the cæcum. After these deepest waves have been running for a few minutes the indentations grow gradually less marked, until at last they are so faint as to be hardly discernible. The final waves are sometimes to be observed only at the end of the transverse colon.

Such a period of antiperistalsis lasts from two to eight minutes, with an average duration of four or five minutes. The periods recur at varying lengths of time; in one instance a period began at 1.38 P.M. and was repeated at 2.06, 2.34, 2.55, 3.15, and at 3.36, when the observation ceased; in another instance a period began at 2.43 P.M., and was repeated at 2.57 and at intervals of from ten to fifteen minutes thereafter while the animal was being watched. The waves have nearly the same rate of recurrence as those in the stomach; about five and a half waves pass a given point in a minute, _i. e._, eleven waves in two minutes. This rate has proved fairly constant in different cats and at different stages in the process of digestion; in one case, however, the waves passed at the rate of nine in two minutes.

The stimulating effect of rectal injections on the movements of the small intestine has already been noted. Enemata have also pronounced stimulating action on the antiperistalsis of the colon. Usually the almost immediate result of a rectal injection of warm water is the appearance of deep antiperistaltic waves, which often continue running for a long period. In one case, after an injection of 50 c.c. of warm water, the waves followed one another with monotonous regularity during an observation lasting an hour and twenty minutes. The manner in which this antiperistaltic mechanism affects nutrient enemata introduced into the bowel will be discussed in the section devoted to the question of antiperistalsis.

These constrictions passing backward over the colon do not force the normal contents back through the valve into the small intestine again. I have seen hundreds of such constrictions, and only twice have there been exceptions to this rule,--once under normal conditions, when a small mass slipped back into the ileum, and at another time when a large amount of water had been introduced into the colon. The importance of the competence of the ileocæcal valve is now apparent; indeed, antiperistalsis in the colon gives new meaning and value to the location of a valve at the opening of the ileum. For, inasmuch as the valve is normally competent, the constrictions repeatedly coursing towards it force the food before them into a blind sac. The effect on the food must be the same as the effect seen in the stomach when the pylorus remains closed before the advancing waves. The food is pressed forward by the approach of each constriction; but since it cannot go onward in the blind sac, and is, moreover, subjected to increasing pressure as the constriction comes nearer, it is forced into the only way of escape, _i. e._, away from the cæcum through the advancing constricted ring. About twenty-five waves affect every particle of food in the colon in this manner during each normal period of antiperistalsis. The result must be again a thorough mixing of the contents and a bringing of these contents into close contact with the absorbing wall--a process which has already been variously repeated many times in the stomach and in the small intestine.

Two other movements have been observed in the ascending colon, but they are rare appearances. The first of these was a serial sectioning of the contents noticed in an animal given castor oil with the food. A constriction separated a small segment in the cæcum; another constriction then cut off a segment just above the first, and with the disappearance of the first constriction the two separated segments united. A third segmentation took place above the second, and the changes occurred again. Thus the whole

mass was sectioned from one end to the other; and no sooner was that finished than the process began again and was repeated several times. A slight modification of this movement was observed in a colon containing very little food. The mass was pressed and partially segmented in the manner characteristic of the small intestine, and was thus again and again spread along the ascending colon, and each time swept back into a rounded form by antiperistalsis. The second of the two movements mentioned above consisted in a gentle kneading of the contents. This was caused by broad constrictions appearing, relaxing, appearing, relaxing, over and over again, in the same place. When several of these regions were active at the same time, they gave the food in the colon the appearance of a restless undulatory mass. Once a constriction occurred and remained permanently in one place, while the bulging parts on either side of it pulsated alternately, at the rate of about eighteen times in a minute, with the regularity of the heart-beat. Although these phenomena are somewhat striking, they are not usual, and are in no way so important as the antiperistalsis.

The changes when food enters the colon.--The passage of food through the ileocæcal valve seems to stimulate the colon to activity. As food is nearing the ileocæcal valve the large intestine is usually quiet and relaxed (Fig. 6, 4.00), though occasionally indefinite movements are to be observed; and sometimes just before the food reaches the end of the ileum the circular fibres of the colon in the region of the valve contract strongly, so that a deep indentation is present there. The indentation may persist several minutes; it disappears as the muscles relax just previous to the entrance of the food. The food is moved slowly along the ileum and is pushed through the valve into the colon. The moment it has entered a strong contraction takes place all along the cæcum and the beginning of the ascending colon, pressing some of the food onward, and a moment later deep antiperistaltic waves (Fig. 6, 4.03) sweep down from the transverse colon and continue running until the cæcum is again normally full, _i. e._, for two or three minutes.

[Illustration: FIGURE 6.--Tracings showing changes when food enters the colon and also the first tonic constriction. 4.00, the colon relaxed as food approaches in the ileum. 4.03, the colon contracted and traversed by antiperistaltic waves after the food has entered.]

The appearance of tonic constrictions.--It has already been noted that as the food accumulates in the ascending colon it is at first confined to this region by antiperistaltic waves. With further accessions, however, the contents naturally must be pressed more and more into the transverse and descending colon. In the early stages of this accumulation, while the food lies chiefly in the ascending colon,

A

TREATISE ON BREAD,

AND

BREAD-MAKING.

BY SYLVESTER GRAHAM.

“Bread strengtheneth man’s heart.”—HOLY WRIT.

BOSTON: LIGHT & STEARNS, 1 CORNHILL. 1837.

Entered according to Act of Congress, in the year 1837, by LIGHT & STEARNS, in the Clerk's Office of the District Court of Massachusetts.

CONTENTS.

HISTORY OF BREAD.

Primitive food of man. Bruising and grinding grain. Baking. Invention of leavened bread. Bread among the Greeks and Romans—among the Hebrews. Simplicity of the bread now used in many countries.

9–16

LAWS OF DIET.

Reasons why food in its natural state would be the best. Concentrated nutriment. Interesting experiments on animals. Mixtures of food. Leavened and unleavened bread. Qualifications of the best bread.

17–30

MATERIAL OF BREAD.

Wheat. Extent of climate favorable to it. Injured by improper tillage. Removal of impurities. Washing of grain. Separation of the bran from the nutrient particles improper. Ancient Roman bread. Public bakers. Use of bad flour. Adulterations. Poisonous agents used to disguise them.

31–50

PROPERTIES OF BREAD.

Superfine flour injurious—a probable cause of some common disorders. Objections to coarse bread. Its medical properties. Extensive experiments of its use, by soldiers and others. Use among European peasantry. Selection, preservation and grinding of wheat.

51–72

FERMENTATION.

Chemical composition of flour. Yeast—modes of preparing it. Substitutes for it. Fermentation, and its products. Vinous, acetous and putrefactive fermentation.

73–86

PREPARATION OF BREAD.

Mixing. Much kneading necessary. Rising, or fermentation. Use of alkalies—saleratus and soda. Baking. Ovens. Alcohol in bread. Preservation of bread.

87–102

WHO SHOULD MAKE BREAD.

Making bread by rule. Bakers. Domestics. Sour bread. An anecdote. Mrs. Van Winkle. Bad bread need not be made. How cake is made. Bread-making a drudgery. Excellent example of a mother. Eating bad bread. Importance of having good bread.

103–126

VARIETIES OF BREAD.

Rye bread. Indian meal bread. Use of sour milk or butter-milk. Acids. Family grinding.

127–131

PREFACE.

There are probably few people in civilized life, who—were the question put to them directly—would not say, that they consider bread _one_ of the most, if not the most important article of diet which enters into the food of man. And yet there is, in reality, almost a total and universal carelessness about the character of bread. Thousands in civic life will, for years, and perhaps as long as they live, eat the most miserable trash that can be imagined, in the form of bread, and never seem to think that they can possibly have anything better, nor even that it is an evil to eat such vile stuff as they do. And if there is occasionally an individual who is troubled with some convictions that his bread is not quite what it should be, he knows not how to remedy the difficulty; for it is a serious truth, that, although nearly every human being in civilized life eats bread of some kind or other, yet scarcely any one has sufficient knowledge of the true principles and processes concerned in bread-making, and of the actual causes of the bad qualities of bread, to know how, with any degree of certainty, to avoid bad and secure good bread.

I have thought, therefore, that I could hardly do society a better service, than to publish the following treatise on a subject which, whether people are aware of it or not, is, in reality, of very great importance to the health and comfort of every one.

It has been prepared for the press with more haste, under more embarrassments from other engagements, and with less severity of revision, than I could wish. Yet, whatever may be its defects of arrangement, method or style, I have taken care to have the principles correct, and the instructions such as, if attended to, will enable every one who is heartily devoted to the object, to make good bread.

I must, however, acknowledge, that I have very little expectation that proper attention will be paid to this subject, so long as the dietetic habits of society continue to be what they are. While the various preparations of animal food constitute so important a portion of human aliment, the quality of bread will be greatly disregarded and neglected, and people will continue almost universally to be cursed with poor bread.

Nevertheless, I trust some good will be done by the little work I now send out; and I am not without hope, that it will be the means of a considerable improvement in the quality of bread, and, as a natural and necessary consequence, an improvement in the health and happiness of those who consume it.

That it may prove thus beneficial to my fellow creatures in a high degree, is my hearty and fervent desire.

S. GRAHAM.

NORTHAMPTON, APRIL 12, 1837.

TREATISE ON BREAD.

HISTORY OF BREAD.

Primitive food of man. Bruising and grinding grain. Baking. Invention of leavened bread. Bread among the Greeks and Romans—among the Hebrews. Simplicity of the bread now used in many countries.

In the English version of the sacred scriptures, the term Bread is frequently used to signify vegetable food in general. Thus in Gen. iii, 19, the Lord says to Adam—“In the sweat of thy face shalt thou eat bread (or food) till thou return to the ground.” See also Gen. xviii, 5, and xxviii, 20, and Ex. ii, 20.

The most extended sense of the word, however, according to general usage, comprehends all farinaceous vegetable substances which enter into the diet of man; such as the farinaceous seeds or grain, nuts, fruit, roots, &c. And in this extended sense, Bread, in some form or other, has been the principal article in the diet of mankind, from the earliest generations of the human race, to the present time; except among the few, small and scattered tribes, which have, perhaps, ever since the days of Noah, in different parts of the earth, subsisted mainly on animal food.

It is nearly certain that the primitive inhabitants of the earth, ate their food with very little, if any artificial preparation.

The various fruits, nuts, seeds, roots, and other vegetable substances on which they fed, were eaten by them in their natural state, with no other grinding than that which was done by the teeth.

As the human family increased, and population became more dense and extended, and providential measures more necessary, the condition and circumstances of society gradually led to the invention and adoption of the simple, and, at first, rude arts of domestic life. Among these, was that of bruising the harder articles of their food, such as nuts and seeds, or grain, on flat stones, selected and kept for the purpose. By constant use, these stones in time became hollowed out; and being thereby rendered more convenient, men at length began to form mortars and pestles from stones; and probably the next step was the construction of the rude kind of hand-mills, which continued in use for many centuries; and indeed, which, with the stone mortars, have, throughout all ages and in almost every portion of the earth, been used in the ruder states of society.

When men became acquainted with the use of fire, they probably often parched their corn or grain before they pounded it; and afterwards, they learned to mix it with water into the consistency of dough, and to bake this, in an unleavened or unfermented state, on flat stones before the fire, or in the hot ashes or hot earth, or in the rude ovens which they formed, by digging holes in the earth, into which they put heated stones, and slightly covered them with leaves or grass, and then laid in the article they wished to bake, and over this strewed some leaves, and then covered the whole with earth.[A]

This kind of unleavened bread, undoubtedly constituted a very important, if not the principal article of artificially prepared food in the diet of the primitive inhabitants of the earth, for many centuries; and the same, or very nearly the same kind of bread continued in general use down to the days of Abraham; and it is probable that the unleavened bread used by his descendants at the feast of the Passover, before and after they left Egypt, was of the same kind.

It is hardly possible, however, that it could have been otherwise, than that, at a much earlier period, larger quantities of this dough were occasionally made, than were immediately baked, and consequently portions of it were suffered to stand and ferment; and by this means, men were in process of time learned to make leavened, or raised bread.

At how early a date, loaf or raised bread came into common use, it is impossible now to ascertain with any considerable degree of precision. The scriptures do not afford us any evidence that Abraham was accustomed to such bread; but the fact that Moses, at the institution of the supper of the Passover, the night before the Jews left Egypt, commanded them strictly to abstain from leavened bread, and to eat only the unleavened, proves conclusively, that the Israelites at least, were then accustomed to fermented, or raised bread.

Neither history nor tradition enables us to speak with any degree of confidence in regard to the period at which other nations became acquainted with the art of bread-making; but from all that has come down to us from ancient times, we learn that the primitive generations of every nation, subsisted on fruits and other products of the vegetable kingdom, in their uncooked or natural state.

“The Greeks assert that they were taught the art of making bread by their god, Pan; and Pliny informs us that this art was not known at Rome till near six hundred years after the foundation of that city. The Roman armies, he says, on their return from Macedonia, brought Grecian bakers into Italy. Before this time, the Romans prepared their meal in a kind of pap or soft pudding; and on this account Pliny calls them pap eaters.”

But though the Egyptians and Israelites were probably among the earliest portions of the human family, who became acquainted with the art of making loaf or raised bread, the quality of their bread continued to be exceedingly simple and coarse for many generations.

Even after the establishment of the Hebrew nation in Palestine—in the most splendid days of Jerusalem—at the period of the highest refinement of the Jews, in the arts of civil and domestic life, their fine flour, from which their choicest bread and cakes were made, was, in comparison with modern superfine flour, extremely coarse,—ground mostly by females, in hand-mills constructed and kept for that purpose.

From Rome the art of bread-making very slowly found its way over considerable portions of Europe. A thousand years after Julius Cæsar first entered Britain, the rude people of that country were little acquainted with raised bread. “Even at present,” says Prof. Thomson, “loaf bread is seldom used except by the higher classes of inhabitants, in the northern countries of Europe and Asia.”

In Eastern and Southern Asia, rice constitutes the principal bread-stuff; and this is generally prepared with great simplicity. In Middle and Western Asia, and in Africa, bread, though made of different kinds of grain, is prepared with almost equal simplicity. In Scotland, Ireland, and indeed throughout Europe generally, barley, oats, rye, potatoes, peas, beans, chesnuts, and other farinaceous vegetables, constitute the bread-stuff of most of the laboring people, or peasantry. In the islands of the Pacific and Southern oceans, the bread of the inhabitants consists of the plantain, bananas, yams, bread-fruit, and other like vegetables, simply roasted, baked, or boiled.

Bread, therefore, of some kind or other, made of some of the farinaceous products of the vegetable kingdom, has probably, in almost every portion of the world, and every period of time, been one of the first, and most important, and universal articles of food, artificially prepared by cooking, which has entered into the diet of mankind; and hence it has with great propriety been called “the staff of life.”

LAWS OF DIET.

Reasons why food in its natural state would be the best. Concentrated nutriment. Interesting experiments on animals. Mixtures of food. Leavened and unleavened bread. Qualifications of the best bread.

If man were to subsist wholly on alimentary substances in their natural state, or without any artificial preparation by cooking, then he would be obliged to use his teeth freely in masticating his food; and by so doing, not only preserve his teeth from decay, and keep them in sound health, but at the same time, and by the same means, would he thoroughly mix his food with the fluid of his mouth, and thus prepare it both for swallowing and for the action of the stomach, and by the same means also, he would be made to swallow his food slowly, as the welfare of the stomach and of the whole system requires he should.

Again, if man were to subsist wholly on uncooked food, he would never suffer from the improper temperature of his aliment. Hot substances taken into the mouth, serve more directly and powerfully to destroy the teeth, than any other cause which acts immediately upon them; and hot food and drink received into the stomach, always in some degree debilitate that organ, and through it, every other organ and portion of the whole system; diminishing, as an ultimate result, the vital power of every part—impairing every function, and increasing the susceptibility of the whole body to the action of disturbing causes, and predisposing it to disease. Again, if man were to subsist entirely on food in a natural state, he would never suffer from concentrated aliment. Every substance in nature which God has prepared for the food of man, consists of both nutritious and innutritious matter. The proportions vary in different kinds of food. Thus in a hundred pounds of potatoes, there are about twenty-five pounds of nourishing matter; while in a hundred pounds of good wheat there are about eighty pounds of nourishing matter. There are a few products of the vegetable kingdom which are still higher in the scale of nutriment, than wheat; and on the other hand there is a boundless variety ranging below wheat, extending down to three or four per cent. of nourishment. But nature, without the aid of human art, produces nothing for the alimentary use of man which is purely a concentrated nutrient substance. And God has constructed man in strict accordance with this general economy of nature. He has organized and endowed the human body with reference to the condition and qualities of those substances in nature, which He designed for the food of man. And consequently, while man obeys the laws of constitution and relation which should govern him in regard to his food, he preserves the health and integrity of his alimentary organs, and through them of his whole nature; and so far as his dietetic habits are concerned, secures the highest and best condition of his nature. But, if he disregards these laws, and by artificial means greatly departs from the natural adaptation of things, he inevitably brings evil on himself and on his posterity.

It has been fully proved that “bulk, or a due proportion of innutritious matter in our food, is quite as important to health as nourishment.” Human beings may subsist from childhood to extreme old age on good potatoes and pure water alone, and enjoy the best and most uninterrupted health, and possess the greatest muscular power and ability to endure protracted fatigue and exposure. But if the purely nutrient matter of the potato be separated out by artificial means, and human beings, fed exclusively on this concentrated form of aliment and pure water, they will soon perish, because the alimentary organs of man are not constituted and endowed for such kinds of food. And this is true of all animals, in the higher orders, at least.

We know that dogs fed on sugar and water, gum and water, fine flour bread and water, or any other kind of concentrated aliment, will soon languish, and droop, and emaciate, and die; but if a due proportion of proper innutritious substance be mixed with these concentrated forms of aliment, the dogs will subsist on them and remain healthy. So if horses, cows, deer, sheep, and other grass-eating animals be fed on grain alone, they will soon lose their appetite and begin to droop, and will shortly perish; but if a due proportion of straw or shavings of wood be given them with their grain, they will continue to do well. Man is affected in the same

manner. He cannot long subsist on purely nutritious substances. And the reason is not because these substances have no azote or nitrogen in them; nor is it because man _necessarily_ requires a variety of alimentary substances, but simply and exclusively because the anatomical construction and vital powers of the alimentary organs, are constitutionally adapted to alimentary substances which consist of both nutritious and innutritious matter; and therefore a due proportion of innutritious matter in the food of man is as essential to the welfare of his alimentary organs, as a due proportion of nourishment is to the support of his body.

Again, if man subsisted wholly on uncooked food, he would not only be preserved from improper concentrations, but also from pernicious combinations of alimentary substances. The alimentary organs of man, like those of the horse, ox, sheep, dog, cat, and most or all other animals of the higher orders, if not in fact, of all other animals without limitation, possess the vital capability of so accommodating themselves to emergencies, that they can be made to digest almost every vegetable and animal substance in nature; and they can, by long training, be educated to digest a mixture of these substances at the same time. Nevertheless it is incontestibly true, that the alimentary organs of man and of all other animals, can manage one kind of food at a time better than a mixed ingestion; for it is impossible that the solvent fluids secreted by the stomach and other organs belonging to the alimentary apparatus, should be at the same time equally well adapted to entirely different kinds of food.

I do not say that the alimentary organs of man cannot, by long habit, be brought into such a condition as that, while that condition remains, they will not manage a mixed ingestion of animal and vegetable food, with more immediate comfort and satisfaction to themselves and the individual, than they will an ingestion of pure vegetable food. But this does not militate against the general principle in the least; for it is nevertheless true, that the same organs are capable of being brought into a condition in which they will manage an ingestion of unmixed food of either kind, with less embarrassment and injury to themselves and the whole system, than they can the mixed food in any condition. Hence it is a general law of nature, concerning the dietetic habits of man, that simplicity of food at each meal is essential to the highest well-being of the individual and of the race.

God has unquestionably provided a great and rich variety of substances for man's nourishment and enjoyment; but it is equally certain that he did not design that man should partake of all this variety at a single meal, nor in a single day, nor season—but from meal to meal, from day to day, and from season to season, varying his enjoyment in strictest consistency with the great laws of his nature. And hence all artificial combinations of alimentary substances, and particularly those of a heterogeneous kind, and yet more especially the concentrated forms, must be more or less pernicious to the alimentary organs, and through them to the whole system.

Finally, if man subsisted wholly on uncooked food, the undepraved integrity of his appetite, his thorough mastication and slow swallowing, and his simple meal, would greatly serve to prevent his overeating, and thus save him from the ruinous effects of one of the most destructive causes operating in civic life.

Whatever may be the material, therefore, from which bread is made, when the artificial preparation is of that simple character which leaves the proportions of nutritious and innutritious properties, as nature combined them, and effects little change in the nutritious principles, and retains the natural requisition for the function of the teeth, and thus secures the proper chewing of the food and the mixing of it with the fluids of the mouth, and swallowing of it slowly, the artificial process militates very little, if at all, against any of the physiological or vital interests of the body. But if our artificial process of bread-making, concentrates the nutrient properties, and destroys the due proportion between the bulk and nourishment, and forms improper changes and combinations in the nutrient elements, and does away the necessity for mastication or chewing, and presents the food in too elevated a temperature, or too hot, and enables us to swallow it too rapidly, with little or no exercise of the teeth, and without properly mixing it with the fluids of the mouth, the artificial process or cooking is decidedly and often exceedingly inimical, not only to the vital interests of the alimentary organs, but of the whole human system.

In all civilized nations, and particularly in civic life, bread, as I have already stated, is far the most important article of food which is artificially prepared; and in our country and climate, it is the most important article that enters into the diet of man; and therefore it is of the first consideration, that its character should, in every respect, be as nearly as possible, consistent with the laws of constitution and relation established in our nature; or with the anatomical construction and vital properties and powers and interest of our systems.

If we contemplate the human constitution in its highest and best condition,—in the possession of its most vigorous and unimpaired powers—and ask, what must be the character of our bread in order to preserve that constitution in that condition? the answer most indubitably is, that the coarse unleavened bread of early times, when of proper age, was one of the least removes from the natural

state of food,—one of the simplest and most wholesome forms of artificial preparations, and best adapted to fulfil the laws of constitution and relation; and therefore best adapted to sustain the most vigorous and healthy state of the alimentary organs, and the highest and best condition of the whole nature of man, as a general and permanent fact; and hence it is very questionable whether loaf or raised bread can be made equally conducive to all the interests of our nature, with the simple unleavened bread.

I am aware that many professional men entertain a very different opinion on this subject, and speak of unleavened bread as being less nourishing and less easily digested. This may be true to a limited extent, in special cases of impaired and debilitated alimentary organs; but I am confident that as a general fact the notion is entirely erroneous.

“The whole people of Asia,” says Dr. Cullen, “live upon unfermented rice. The Americans, before they became acquainted with the Europeans, employed, and for the most part, still employ their maize in the same condition. Even in Europe, the employment of unfermented bread, and unfermented farinaceæ in other forms, is still very considerable, and we are ready to maintain that the morbid consequences of such a diet are very seldom to be observed. In Scotland, nine tenths of the lower classes of people—and that is the greater part of the whole—live upon unfermented bread and unfermented farinaceæ in other forms, and at the same time, I am of opinion that there are not a more healthy people anywhere to be found. We give it to all classes and both sexes with advantage.”

It is incontestibly true, that if two portions of the same kind of wheat meal be taken and made, the one into unleavened and the other into leavened bread, and both be eaten warm from the oven, the leavened bread will prove much more oppressive and difficult to manage in the stomach than the unleavened. But aside from the changes that are produced by the process of fermentation, there are many other considerations why unleavened bread of a proper quality and age, is better adapted to sustain the alimentary organs and general constitution of man, in their highest and best condition.

Nevertheless, it is very certain, that loaf or raised bread can be made so nearly in accordance with the vital laws and interests of our bodies, as scarcely to militate against them in any perceptible or appreciable degree. And when I say this, I mean not merely its effects on the health and longevity of a single individual, but its effects upon the human constitution, through successive generations, for a thousand years or more.

As a general criterion or rule, then, in regard to the character of bread, we perceive that the most perfect loaf or raised bread, is that which, being made of the best material, is light, and sweet, and well baked, and still most nearly retains all the natural proportions and properties of the original material.

MATERIAL OF BREAD.

Wheat. Extent of climate favorable to it. Injured by improper tillage. Removal of impurities. Washing of grain. Separation of the bran from the nutrient particles improper. Ancient Roman bread. Public bakers. Use of bad flour. Adulterations. Poisonous agents used to disguise them.

Among the materials used for making bread in our country—and, in fact, of all the known productions of the vegetable kingdom in any country, wheat is decidedly the best; and it is a remarkable fact, that wheat comes nearer to man than perhaps any other plant, in its power of becoming adapted to different climates, over a wide extent of the earth’s surface, so that it may almost be said that wherever the human species can flourish, there wheat can be cultivated.

“It is not certainly known,” says Prof. Thomson, “in what country wheat was first produced. Mr. Bruce informs us that he found it growing wild in Abyssinia; and in his opinion, that kingdom is the native country of the plant. It would seem,” continues the Professor, “to be originally an African plant, since it thrives best in Barbary and Egypt; and perhaps the mountains of Abyssinia, though within the torrid zone, may not differ much in point of climate, from the more northern plains of Egypt. Wheat is perhaps cultivated over a greater extent of the globe than any other plant. Excellent crops are raised as far north as Sweden, in latitude 60°; it is cultivated in the East Indies, considerably within the limits of the torrid zone; and in the North of Hindostan, it constitutes a chief article in the food of the inhabitants. In India, however, the plant seems to have deteriorated. It is always dwarfish, and the crop is said to be less abundant than in more northern climates.” Yet a cold climate is not most genial to the nature of this plant. “The wheat of France is superior to that of England; the wheat of Italy is still better than that of France; and perhaps the best of all is raised in Barbary and Egypt.”

Excellent wheat is raised in the southern, and western, and middle portions of the United States; and even in the northern and eastern parts of New England, very fine crops have been produced.

But the wheat and other cultivated products of the vegetable kingdom appropriated to the nourishment of man, like those on which our domestic animals subsist, are too generally, in civilized life, very considerably deteriorated, as to their wholesomeness, by the improper tillage of the soil. I have no doubt that it is true, as stated by those who have made the experiment, that the flour of wheat, raised on a cultivated soil recently dressed with crude, stable manure, may readily be distinguished by its odor, from the flour of wheat raised on a new and undepraved soil, or from that raised on a cultivated soil which has been dressed with properly digested manure. And if such and similar results of improper tillage can become the sources of serious evil to the human family, through their effects on the flesh of animals which man devours, and on the milk and butter which he consumes, surely the immediate effects of such a deteriorated vegetable aliment on the human system, must be very considerable.

They who have never eaten bread made of wheat, recently produced by a pure virgin soil, have but a very imperfect notion of the deliciousness of good bread; such as is often to be met with in the comfortable log houses in our western country. It is probably true that the new soil, in its virgin purity, before it becomes exhausted by tillage, and debauched by the means which man uses to enrich and stimulate it, produces most, if not all kinds of vegetables appropriate for human aliment, in a more perfect and healthy state, than any soil which has been long under cultivation, can be made to do. Nevertheless, by a proper application of physiological principles to agriculture, many of the evils which now result from improper tillage may easily be avoided, and the quality of all those vegetable substances which enter into the diet of man may be very greatly improved, both in regard to wholesomeness and deliciousness.

But while the people of our country are so entirely given up as they are at present, to gross and promiscuous feeding on the dead carcasses of animals, and to the untiring pursuits of wealth, it is perhaps wholly in vain for a single individual to raise his voice on a subject of this kind. The farmer will continue to be most eager to increase the number of his acres, and to extort from those acres the greatest amount of produce, with the least expense of tillage, and with little or no regard to the quality of that produce in relation to the physiological interests of man; while the people generally, are contented to gratify their depraved appetites on whatever comes before them, without pausing to inquire whether their indulgences are adapted to preserve or to destroy their health and life. Yet if some one does not raise a voice upon this subject which shall be heard and heeded, there will soon reach us, as a nation, a voice of calamity which we shall not be able to shut our ears against, albeit we may in the perverseness of our sensualism, incorrigibly persist in disregarding its admonitions, till the deep chastisements of outraged nature shall reach the very “bone and marrow” of the human constitution, and fill our land with such a living rottenness, as now in some other portions of the earth, renders human society odious and abominable.

Whether, therefore, my voice shall be heard and heeded or not, I will obey the dictates of my sense of duty, and solemnly declare that this subject demands the prompt and earnest attention of every agriculturist and of every friend to the common cause of humanity; for it is most certain, that until the agriculture of our country is conducted in strict accordance with physiological truth, it is not possible for us to realize those physical, and intellectual, and moral, and social, and civil blessings for which the human constitution and our soil and climate are naturally capacitated.

When proper attention has been paid to the character of the wheat itself, the next thing is to see that it is thoroughly cleansed.

Sometimes, in consequence of the peculiarities of the season, or climate, or soil, or some other cause, there will be a species of disease affecting the wheat and other grains; and this may be of such a character as not easily to be removed nor counteracted by any means; but more generally the rust, and smut, and dust, which attach themselves to the skin of the grain, may, by proper care, be so far removed, as at least to render the meal or flour far more pure and wholesome than it otherwise would be. And here let me remark, that they are greatly deceived, who suppose that the bolting cloth which separates the fine flour from the outer skin or bran, also separates the impurities attached to the outer skin from the flour. By the process of grinding, these impurities are rubbed from the outer skin, and made quite as fine as any portion of the flour, and for the most part pass with the fine flour through the bolting cloth.

To remedy this, it is perhaps generally true, that in large flouring establishments, a kind of smut or scouring mill is in operation, through which the wheat passes, and is pretty thoroughly rubbed or scoured without being broken; and after this, it passes through a screen or winnowing mill, and thus is tolerably well cleansed and prepared for grinding. Yet this process by no means renders the wheat so perfectly clean and wholesome as washing.

Those who have given little attention to this subject, will probably think that the trouble of washing all their bread-stuff before it is ground, would be much greater than any benefit which would result from it. But a short experience in the matter, would convince every one who has a proper regard for the character of his bread, that the trouble of washing his grain bears no comparison to the improvement effected by it. Indeed, they who become accustomed to washing their grain, will soon cease to regard it as a trouble; and the improvement in the whiteness and sweetness of their bread will be so great, that they would be extremely unwilling to relinquish the practice.

When people are so situated that they can have things as they wish, they will also find that their bread is much richer, if the grain is ground but a short time before it is cooked.

The best way, therefore, is, for every family to raise or purchase a sufficient quantity of the best new wheat that can be produced by proper tillage in a good soil, and put that away in clean casks or bins, where it will be kept perfectly dry and sweet; and, according to the size of the family, take, from time to time, as they need it, one or two bushels, and wash it thoroughly but briskly in two or three waters, and then spread it out on a drying sheet or table, made for the purpose, and which is considerably inclined, so that the water remaining with the wheat will easily run off.

The skin or bran of the wheat is so well protected by its own oily property, that little or no water will penetrate it, unless it be suffered to remain in the water much longer than is necessary. Being thinly spread out upon the sheet or table in a good drying day, it will be sufficiently dry in a few hours for grinding. And I say again, let any one who loves good bread, wash his grain a few times in this manner, and he will be very reluctant to return to the use of bread made of unwashed grain.

It would be difficult to ascertain at how early a period in the progress of society, mankind, in the preparation of wheat for bread-making, began to put asunder what God has joined together, and to concentrate the more purely nutrient properties, by separating the flour from the part commonly called the bran. The Bible speaks of fine flour or meal, as a portion of the meat offerings of the temple, but it is not probable this approached very near to the superfine flour of the present time.

We are informed also that the Romans, more than two thousand years ago, had four or five different kinds of bread—one of which was made of the purest flour, from which all the bran was separated. This was eaten only by the rich and luxurious. A second kind, in more common use, was that from which a portion of the bran was taken; and a third kind, which was more generally used than any other, was that which was made of the whole substance of the wheat. A fourth kind was made mostly of the bran, for dogs.

But at whatever period in the history of the race, this artificial process was commenced, certain it is that in direct violation of the laws of constitution and relation which the Creator has established in the nature of man, this process of mechanical analysis is, at the present day, carried to the full extent of possibility; and the farina, and gluten, and saccharine matter of the wheat, are almost perfectly concentrated in the form of superfine flour. Nor is this all—these concentrated nutrient properties of the wheat are mixed and complicated in ways innumerable, with other concentrated substances, to pamper the depraved appetites of man, with kinds of food which always and inevitably tend to impair his health and to abbreviate his life.

Even the bread, which is the simplest form into which human ingenuity tortures the flour of wheat, is, by other causes besides the concentration I have named, too frequently rendered the instrument of disease and death, rather than the means of life and health, to those that eat it.

In cities and large towns, most people depend on public bakers for their bread. And I have no doubt that public bakers, as a body, are as honest and worthy a class of men as any in society. I have no wish to speak evil of any one; and it is always painful to me to find myself compelled, in fidelity to the common cause of humanity, to expose the faults of any particular class of men, when probably every other class in society is as deeply involved in errors which, in the sight of God, evince, at least, an equal degree of moral turpitude.

But public bakers, like other men, who serve the public more for the sake of securing their own emolument than for the public good, have always had recourse to various expedients in order to increase the lucrativeness of their business.

To secure custom and profit at the same time, they have considered it necessary, that a given quantity of flour should be made into a loaf as large and as white as possible, and free from any disagreeable taste, while at the same time it retains the greatest possible weight.

From a variety of causes, the quality and price of flour have always been very unstable. Sometimes the crops are small, or the foreign demand for flour or the home consumption is unusually great, or the season is unfavorable to the health of grain, and the wheat becomes diseased, or the harvest time is unfavorable, and the wheat sprouts before it is secured, or large quantities of flour become soured or musty, or in some other manner damaged.

To counteract these things, and to make the most profitable use of such flour as the market affords them, the public bakers have been led to try various experiments with chemical agents, and there is reason to believe that in numerous instances, they have been too successful in their practices, for the well-being of those who have been the consumers of their bread.

According to treatises on bread-making, which have within a few years past appeared in European scientific journals, “alum, sulphate of zinc, sub-carbonate of magnesia, sub-carbonate of ammonia, sulphate of copper, and several other substances, have been used by public bakers in making bread; and some of these substances have been employed by them to a very great extent, and with very great success in the cause of their cupidity. They have not only succeeded by such means, in making light and white bread out of extremely poor flour, but they have also been able so to disguise their adulterations, as to work in with their flour, without being detected by the consumers, a portion of the flour of beans, peas and potatoes—and even chalk, pipe clay and plaster of Paris, have been employed to increase the weight and whiteness of their bread.”

“The use of alum in bread-making,” says a distinguished chemist, “appears to be very ancient. It is one of those articles which have been the most extensively and successfully used in disguising bad flour, and the various adulterations of bread. Its injurious action upon the health is not to be compared with that of sulphate of copper, and yet, daily taken into the stomach, it may seriously affect the system.”

“Thirteen bakers were condemned on the 27th of January, 1829, by the correctional tribunal of Brussels, for mixing sulphate of copper or blue vitriol with their bread. It makes the bread very white, light, large and porous, but rather tasteless; and it also enables the bread to retain a greater quantity of water, and thereby very considerably increases its weight. A much larger quantity of alum is necessary to produce these effects; but when of sufficient quantity, it strengthens the paste, and, as the bakers say, ‘makes the bread swell large.’”

If the statements of our large druggists can be relied on, the public bakers of our own country probably employ ammonia more freely, at present, than any other substance I have named. Pearlash or saleratus is also used by them in considerable quantities.

But even where these adulterations are not practised, the bakers’ bread is very rarely a wholesome article of diet.

If any dependence is to be placed on the testimony of several of the principal bakers and flour merchants in New York, Boston and other cities, the flour which most of our public bakers work into bread, is of a very inferior quality to what is called good “family flour,” and for which they pay from one to three dollars less per barrel; and they sometimes purchase large quantities of old spoiled flour from New Orleans and elsewhere, which has heated and soured in the barrel, and perhaps become almost as solid as a mass of chalk; so that they are obliged to break it up, and grind it over, and spread it out, and expose it to the air, in order to purify it in a measure from its acid and other bad properties; and then they mix it with a portion of much better flour; and from this mixture they can make, as they say, the very largest and finest looking loaf.[B]

But should the public bakers always use the best of flour, their bread, as a general statement, would still be very inferior to well made domestic bread, in point of sweetness and wholesomeness. Their mode of manufacturing bread—to say the least of it—destroys much of the virtue of the flour or meal; and hence their bread is only palatable—even to those who are accustomed to it—within twelve, or at the longest, twenty-four hours after it is baked.

But I must repeat, that in making these statements, I am not prompted by any unkind feelings towards public bakers; I have no doubt that they are as honest in their calling as any other class of men; but perhaps there is no other class pursuing an interest founded on the necessities of their fellow creatures, whose expedients to increase the lucrativeness of their business, are so immediately and universally injurious to the health of those on whom they depend for support.

If any of my statements are thought to be exaggerated or incorrect, I can only say, that with honest and benevolent intentions, I have diligently sought for the truth; and if I have been in any respect betrayed into error, I have been misinformed by public bakers themselves, who certainly ought to know the truth in this matter; and who could have no conceivable reason for making the general character of their calling appear worse than it really is. Nevertheless, I have no question that there are individuals in every city employed as public bakers, who are too honest—too conscientious—too upright in heart, to be guilty of any practice which they

consider fraudulent or improper.

Still, truth compels me to declare, that if we would have good and wholesome bread, it must be made within the precincts of our own domestic threshold; and by those whose skill and care are exercised more with a view to secure our health and happiness, than their own pecuniary interest.

PROPERTIES OF BREAD.

Superfine flour injurious—a probable cause of some common disorders. Objections to coarse bread. Its medical properties. Extensive experiments of its use, by soldiers and others. Use among European peasantry. Selection, preservation and grinding of wheat.

Whether our bread is of domestic manufacture or made by the public baker, that which is made of superfine flour is always far less wholesome, in any and every situation of life, than that which is made of wheaten meal which contains all the natural properties of the grain.

It is true, that when much flesh is eaten with our bread, or when bread constitutes but a very small and unimportant portion of our food, the injurious effects of superfine flour bread are not always so immediately and distinctly perceived as in other cases. Nevertheless, it is a general and invariable law of our nature, that all concentrated forms of food are unfriendly to the physiological or vital interests of our bodies.

A very large proportion of all the diseases and ailments in civic life, are originated by causes which are introduced into the alimentary canal as articles of diet; and disturbance and derangement of function—obstructions, debility and irritations, are among the most important elements of those diseases.

It is, probably, speaking within bounds, to say that nine tenths of the adults, and nearly as large a proportion of youth in civic life, are more or less afflicted with obstructions and disturbances in the stomach and bowels, and other organs of the abdomen, the symptoms of which are either habitual costiveness or diarrhœa, or an alternation of both; or frequent and severe attacks of what are called bilious colics, &c., &c.; and in children and youth, worms, fits, convulsions, &c. And I cannot but feel confident, that the use of superfine flour bread is among the important causes of these and numerous other difficulties.

I have indeed been surprised to observe, that in the hundreds of cases of chronic diseases of every form and name, which have come to my knowledge within the last five or six years, costiveness of the bowels has in almost every instance been among the first and most important symptoms. And I have never known this difficulty, even after an obstinate continuance of five, ten, twenty or thirty years, fail to disappear in a short time, after the coarse wheaten bread of a proper character has been substituted for that made of superfine flour.

Some physicians and other individuals, without properly examining the subject, have raised several objections against the coarse wheaten bread.

It is said, in the first place, that bran is wholly indigestible, and therefore should never be taken into the human stomach.

This objection betrays so much ignorance of the final causes and constitutional laws, clearly indicated by the anatomical structure and physiological economy of the alimentary organs, that it scarcely deserves the slightest notice. If the digestive organs of man were designed to receive nothing but digestible and nutrient substances, they would have been constructed and arranged very differently from what they are. As we have already seen, everything which nature provides for our sustenance, consists of certain proportions of nutritious and innutritious matter; and a due proportion of innutritious matter in our food is as essential to the health and functional integrity of our alimentary organs, as a due proportion of nutritious matter is to the sustenance of the body.

Another objection is, that although bran may serve, like other mechanical irritants and excitants, for a while, to relieve constipation, yet it soon wears out the excitability of the organs, and leaves them more inactive than before.

Here again, a false statement is urged by inexcusable ignorance; for it is not true that the bran acts in the manner supposed in this objection; nor are the effects here asserted ever produced by it.

It is true, however, that the very pernicious habits of some people, who use the coarse wheaten bread, entirely counteract the aperient effects of the bread; and it is true that others, depending wholly on the virtues of this bread for peristaltic action, and

neglecting all exercise, by their extreme inertness, and indolence, and overeating, bring on a sluggishness, and debility, and constipation of the bowels, and perhaps become severely afflicted with piles, in spite of the natural fitness of the bread to promote regular peristaltic action, and to prevent all these results.

A third objection is, that though the coarse wheaten bread may do very well for those who are troubled with constipation, by mechanically irritating and exciting the stomach and bowels, yet for that very reason it is wholly unfit and improper for those who are afflicted with chronic diarrhœa.

Here is still another objection founded in ignorance of the true physiological and pathological principles which it involves. The truth is, that the coarse wheaten bread, under a proper general regimen, is as excellent and sure a remedy for chronic diarrhœa as for chronic constipation.

I have seen cases of chronic diarrhœa of the most obstinate character, and which had baffled the highest medical skill and every mode of treatment for more than twenty years, yielding entirely under a proper general regimen, in which this bread was the almost exclusive article of food, and not a particle of medicine was used. And I have never known such a mode of treatment to fail of wholly relieving diarrhœa, whether recent or chronic; although a very great number of cases have come under my notice.

It is fully evident, therefore, that the bran does not act on the digestive organs as a mere mechanical irritant; for if it did, it would always necessarily aggravate, rather than alleviate diarrhœa. Nor does it relieve diarrhœa on the principle of a narcotic nor of a stimulant; for the effect of these is always to give an immediate check to that complaint; and in such a manner as to expose the system to a return of it. But the coarse wheaten bread _seems_ to increase the disease for a short time, at first, and then gradually restores the healthy condition and action of the bowels.

The mucilage of wheat bran is probably one of the most soothing substances in the vegetable kingdom, that can be applied to the mucous membrane of the stomach and bowels.

Chronic constipation and chronic diarrhœa, both spring from the same root. Where the constitutional vigor of the alimentary canal is very considerable, continued irritations, resulting in debility, will produce constipation; and these continued causes operating for some time, will often induce such a state of debility and irritability as is attended with diarrhœa:—and in other cases, when this constitutional vigor of the alimentary canal is much less, diarrhœa is far more readily induced, and rendered chronic.

Coarse wheaten bread, then, by its adaptation to the anatomical structure and to the physiological properties and functional powers of our organs, serves to prevent and to remove the disorders and diseases of our bodies, only by preventing and removing irritation and morbid action and condition, and thereby affording the system an opportunity of recovering its healthy and vigorous action and condition. And the thousands of individuals in our own country of every age—of both sexes—of all situations, conditions and circumstances, who within the last six years have been benefited by using the coarse wheaten bread, instead of that made of superfine flour, are living witnesses of the virtues of that bread.

But the testimony in favor of coarse wheaten bread as an important article in the food of man, is by no means limited to our own country nor to modern times.

In all probability, as we have already seen, the first generations of our species, who became acquainted with the art of making bread, continued for many centuries to employ all the substance of the grain, which they coarsely mashed in their rude mortars or mills. And even since mankind began, by artificial means, to separate the bran from the flour, and to make bread from the latter, the more close and discerning observers among physicians and philanthropists, have perceived and asserted, that bread made of fine flour is decidedly less wholesome than that made of the unbolted wheat meal.

Hippocrates, styled the father of medicine, who flourished more than two thousand years ago, and who depended far more on a correct diet and general regimen, both for the prevention and removal of disease, than he did on medicine, particularly commended the unbolted wheat meal bread, “for its salutary effects upon the bowels.” It was a fact well understood by the ancients, that this bread was much more conducive to the general health and vigor of their bodies, and every way better adapted to nourish and sustain them than that made of the fine flour. And accordingly, their wrestlers and others who were trained for great bodily power, “ate only the coarse wheaten bread, to preserve them in their strength of limbs.” The Spartans were famous for this kind of bread; and we learn from Pliny that the Romans, as a nation, at that period of their history when they were the most remarkable for bodily vigor and personal prowess and achievement, knew no other bread for three hundred years. The warlike and powerful nations which overran the Roman Empire, and finally spread over the greater part of Europe, used no other kind of bread than that which

was made of the whole substance of the grain; and from the fall of the Roman Empire to the present day, a large proportion of the inhabitants of all Europe and the greater part of Asia, have rarely used any other kind of bread.

“If you set any value on health, and have a mind to preserve nature,”—said Thomas Tryon, student in physic, in his “Way to Health, Long Life and Happiness,” published in London, in the latter part of the fifteenth century,—“you must not separate the finest from the coarsest flour; because that which is fine is naturally of an obstructive and stopping quality; but, on the contrary, the other, which is coarse, is of a cleansing and opening nature, therefore the bread is best which is made of both together. It is more wholesome, easier of digestion, and more strengthening than bread made of the finest flour. It must be confessed, that the nutrimentive quality is contained in the fine flour; yet, in the branny part is contained the opening and digestive quality; and there is as great a necessity for the one as the other, for the support of health: that which is accounted the worst is as good and beneficial to nature as the best; for when the finest flour is separated from the coarsest and branny parts, neither the one nor the other has the true operations of the wheat meal. The eating of fine bread, therefore, is inimical to health, and contrary both to nature and reason; and was at first invented to gratify _wanton_ and _luxurious_ persons, who are ignorant both of themselves, and the true virtue and efficacy of natural things.”

“Baron Steuben has often told me,” says Judge Peters, “that the peculiar healthfulness of the Prussian soldiers, was in a great measure to be attributed to their ammunition bread, made of grain, triturated or ground, but not bolted; which was accounted the most wholesome and nutritious part of their rations.”[C]

“The Dutch sailors, in the days of their naval glory, were supplied with the same kind of bread.”

“During the war between England and France, near the close of the last century,” says Mr. Samuel Prior, a respectable merchant of Salem, New Jersey—“the crops of grain, and particularly wheat, were very small in England, and the supplies from Dantzic, the Netherlands and Sweden being cut off by the French army, and also the usual supplies from America failing, there was a very great scarcity of wheat in England. The British army was then very extensive, and it was exceedingly difficult to procure provisions for it, both at home and abroad—on land and sea. Such was the demand for the foreign army, and such the deficiency of crops at home and supplies from abroad, that serious fears were entertained that the army would suffer, and that the continental enterprise of the British government would be defeated in consequence of the scarcity of provisions; and every prudential measure by which such a disastrous event could be prevented, was carefully considered and proposed. William Pitt was then prime minister of state, and at his instance, government recommended to the people generally throughout Great Britain, to substitute potatoes and rice as far as possible, for bread, in order to save the wheat for the foreign army. This recommendation was promptly complied with by many of the people. But still the scarcity was alarmingly great. In this emergency, parliament passed a law (to take effect for two years) that the army at home should be supplied with bread made of unbolted wheat meal, solely for the purpose of making the wheat go as far as possible, and thus saving as much as they could from the home consumption, for the better supply of the army on the continent.

“Eighty thousand men were quartered in barracks in the counties of Essex and Suffolk. A great many were also quartered throughout the towns, at taverns, in squads of thirty or forty in a place. Throughout the whole of Great Britain, the soldiers were supplied with this coarse bread. It was deposited in the store-rooms with the other provisions of the army; and on the day that it was baked, and at nine o’clock the next morning, was distributed to the soldiers—who were at first exceedingly displeased with the bread, and refused to eat it, often casting it from them with great rage, and violent execrations. But after two or three weeks they began to be much pleased with it, and preferred it to the fine flour bread.

“My father,” continues Mr. P., “whom I have often heard talk these things over, was a miller and a baker, and resided in the county of Essex, on the border joining Suffolk, and near the barracks containing the eighty thousand soldiers. He contracted with government, to supply the eastern district of the county of Essex, with the kind of bread I have mentioned: and he used always to send me with it to the depositories on the day it was baked: and though I was then a youth, I can still very distinctly remember the angry looks and remarks of the soldiers, when they were first supplied with it. Indeed they often threw their loaves at me as I passed along, and accompanied them with a volley of curses. The result of this experiment was, that not only the wheat was made to go much farther, but the health of the soldiers improved so much and so manifestly, in the course of a few months, that it became a matter of common remark among themselves, and of observation and surprise among the officers and physicians of the army. These gentlemen at length came out with confidence and zeal on the subject, and publicly declared that the soldiers were never before so healthy and robust; and that disease of every kind had almost entirely disappeared from the army. The public papers, were for months filled with recommendations of this bread, and the civic physicians almost universally throughout Great Britain, pronounced it far the most healthy bread that could be eaten, and as such, recommended it to all the people, who very extensively

followed the advice:—and the coarse wheaten bread was very generally introduced into families—female boarding schools, and indeed all public institutions. The nobility also generally used it; and in fact, in many towns, it was a rare thing to meet with a piece of fine flour bread. The physicians generally asserted that this wheaten bread was the very best thing that could be taken into the human stomach, to promote digestion and peristaltic action; and that it, more than anything else, would assist the stomach in digesting other things which were less easily digested, and therefore they recommend that a portion of it should be eaten at every meal with other food.

“Still, after this extensive experiment had been made with such happy results, and after so general and full a testimony had been given in favor of the coarse wheaten bread, when large supplies of superfine flour came in from America, and the crops at home were abundant, and the act of parliament in relation to the army became extinct, most of the people who had before been accustomed to the use of fine flour bread, now by degrees returned again to their old habits of eating fine bread. Many of the nobility, however, continued to use the coarse bread for a number of years afterwards. General Hanoward, Squire Western, Squire Hanbury and others living near my father’s, continued to use the bread for a long time, and some of them still used it when I left home and came to America, in 1816.”

The testimony of sea captains and old whalemen is equally in favor of wheaten bread. “I have always found,” said a very intelligent sea captain of more than thirty years’ experience, “that the coarser my ship bread, the healthier my crew is.”

A writer in Rees’ Cyclopædia, (article Bread) says—“The inhabitants of Westphalia, who are a hardy and robust people, and capable of enduring the greatest fatigues, are a living testimony to the salutary effects of this sort of bread; and it is remarkable that they are very seldom attacked by acute fevers, and those other diseases which are from bad humors.”

In short, as I have already stated, the bread of a large portion of the laboring class, or peasantry, throughout Europe, Asia and Africa, and the islands of the ocean, whether leavened or unleavened—whether more or less artificially prepared, is made of the whole substance of the grain from which it is manufactured: and no one who is sufficiently enlightened in physiological science to qualify him to judge correctly in this matter, can doubt that bread made in the best manner from unbolted wheat meal, is far better adapted to the anatomical structure and physiological powers of the alimentary organs of man, than bread made of superfine wheat flour; and consequently, the former is far more conducive to the health and vigor and general well-being of man than the latter.

If, therefore, mankind will have raised bread which in every respect most perfectly conforms to the laws of constitution and relation established in their nature, and is most highly conducive to the welfare of their bodies and souls, then must it be well made, well baked, light and sweet bread, which contains all the natural properties of the wheat. And if they will have this bread of the very best, and most wholesome kind, they must, as I have already stated, see that the soil from which their wheat is raised, is of a proper character, and is properly tilled,—that the wheat is plump—full-grown—ripe, and free from rust and other diseases; and then, before it is ground, they must see that it is thoroughly cleansed, not only from chaff, cockles, tares, and such like substances, but also from all smut, and every kind of impurity that may be attached to the skin of the kernel. And let every one be assured that this is a matter which really deserves all the attention and care that I suggest.

If human existence is worth possessing, it is worth preserving; and they who have enjoyed it as some have done, and as all the human family are naturally endowed with the capabilities to enjoy it, certainly will not doubt whether it is worth possessing; nor, if they will properly consider the matter, can they doubt that its preservation is worthy of their most serious and diligent care.

And when they perceive how intimately and closely the character of their bread is connected with the dearest interests of man, they will not be inclined to feel that any reasonable amount of care and labor is too much to be given to secure precisely the right kind of bread.

I repeat, then, that they who would have the very best bread should certainly wash their wheat, and cleanse it thoroughly from all impurities, before they take it to the mill; and when it is properly dried, it should be ground by sharp stones which will cut rather than mash it: and particular care should be taken that it is not ground too fine. Coarsely ground wheat meal, even when the bran is retained, makes decidedly sweeter and more wholesome bread than very finely ground meal. When the meal is ground, it should immediately be spread out to cool before it is put into sacks or casks:—for if it is packed or enclosed in a heated state, it will be far more likely to become sour and musty. And I say again, where families are in circumstances to do wholly as they choose in the matter, it is best to have but little ground at a time; as the freshly ground meal is always the liveliest and sweetest, and makes the most delicious bread.

When the meal is thus prepared and brought home, whether in a barrel or sack, the next thing to be attended to, is, that it be placed and kept in a perfectly clean, and sweet, and well ventilated meal room. It should on no consideration be put into a closet, or pantry, or store-room, which is seldom aired, and more rarely cleansed; and into which all manner of rubbish is thrown; or even where other kinds of provisions are kept. If the meal be put into a pantry or store-room which is confined and dirty, and into which old boots and shoes, and old clothes and pieces of carpet, and other things of this kind, are thrown—or where portions of vegetable or animal substance, whether cooked or uncooked, are habitually or even occasionally put and permitted to remain, it must be expected, as a matter of course, of necessity, that the quality of the meal will be considerably deteriorated by the impurities with which the air of the place will be loaded, and which will be continually generated there.

People generally have but a sorry idea of what constitutes true cleanliness; but they may be assured that they cannot be too deeply impressed with the importance of keeping their meal room as clean and sweet and well aired as possible.

FERMENTATION.

Chemical composition of flour. Yeast—modes of preparing it. Substitutes for it. Fermentation, and its products. Vinous, acetous and putrefactive fermentation.

Having procured good wheat, cleansed it thoroughly, and got it properly ground, and placed in the meal room, the next step is to take a portion of the meal and manufacture it into good bread. But in order that this may be done in the most certain and perfect manner, it is important that the properties of the meal and the principles concerned in bread-making should be well understood.

According to the statement of Prof. Thomson, of Edinburgh, one pound of good wheat meal contains ten ounces of farina or starch, three ounces of bran, six drams of gluten and two drams of sugar;—and it is because wheat contains such proportions of these substances that it makes the very best loaf bread. The farina or starch is the principal nourishing property;—the saccharine matter or sugar is also highly nutrient; but in the process of making loaf bread, it serves mainly, by its vinous fermentation, to produce the gas or air by which the dough is raised and the bread made light. The gluten is likewise a very nutrient property, but in loaf bread, it principally serves, by its cohesiveness, like gum elastic, or India rubber, to prevent the gas or air formed by the fermentation of the sugar, from escaping or passing off;—and the gas being thus retained, inflates or puffs up the dough, and makes it porous and light. The bran, with its mucilaginous and other properties, not only adds to the nutritiousness of the bread, but eminently serves to increase its digestibility, and to invigorate the digestive organs, and preserve the general integrity of their functions.

The wheat which is raised in Virginia and the southern states generally, contains a larger proportion of gluten than that which is raised in the western part of the state of New York. Hence bakers are able to make a larger loaf of bread out of a pound of southern flour than they can out of a pound of western flour; and consequently some of them have endeavored to make their customers believe that the southern flour is the most profitable. It certainly _is_ the most profitable for the baker; but it is not the most profitable for the consumer.

The next thing indispensably necessary to the making of good bread, is good lively sweet yeast, or leaven, to produce what is called the panary, or more properly, the vinous fermentation of the saccharine matter, or sugar.

Some bread-makers will do best with one kind of yeast or leaven, and some with another. I have generally found that people do best with those materials to which they have been most accustomed; but I am sorry to find so general a dependence on breweries for yeast. To say nothing of the impure and poisonous substances which brewers employ in the manufacture of beer, and which always affect the quality of their yeast, I am confident that domestic yeast can be made of a far superior quality. However light and good in other respects that bread may be which is made with brewers yeast, I have rarely if ever seen any in which I could not at once detect the disagreeable properties of the yeast.

There are various ways of making domestic yeast. One of the simplest, and perhaps the best, is the following, which was communicated to me by one of the best bread-makers I ever saw:

“Put into one gallon of water a double handful of hops;—boil them fifteen or twenty minutes, then strain off the water while it is scalding hot;—stir in wheat flour or meal till it becomes a thick batter, so that it will hardly pour;—let it stand till it becomes about blood warm, then add a pint of good lively yeast, and stir it well; and then let it stand in a place where it will be kept at a temperature of about 70° F. till it becomes perfectly light, whether more or less time is required; and then it is fit for use;—or if it is desired to keep a portion of it, let it stand several hours and become cool; and then put it into a clean jug and cork it tight, and place it in the

cellar where it will keep cool; and it may be preserved good, ten or twelve days, and even longer."

Another way by which yeast when thus made may be preserved much longer, and perhaps more conveniently, is, to take it when it has become perfectly light, and stir in good Indian meal until it becomes a hard dough: then take this dough and make it into small thin cakes, and dry them perfectly, without baking or cooking them at all. These cakes, if kept perfectly dry, will be good for several weeks and even months.

When yeast is needed, take some of these cakes (more or less according to the quantity of bread desired) and break them fine and dissolve them in warm water, and then stir in some wheat flour till a batter is formed, which should be kept at a temperature of about 60° F. till the yeast becomes light and lively, and fitted for making bread.

Others, in making this yeast, originally put into the water with the hops, a double handful of good clean wheat bran, and boil them up together and strain off the water as above described: others again, boil up a quantity of wheat bran without the hops, and make their yeast in all other respects as above described.

The milk yeast is greatly preferred by many; and when it is well managed, it certainly makes very handsome bread. The way of making it is simple. Take a quart of milk fresh from the cow, (more or less according to the quantity of bread desired,)—a little salt is generally added, and some add about half a pint of water blood warm, but this is not essential;—then stir wheat flour or meal into the milk till it forms a moderately thick batter; and then cover it over, and place it where it will remain at a temperature of from 60° to 70° F. till it becomes perfectly light. It should then be used immediately: and let it be remembered that dough made with this yeast will sour sooner than that made with other yeast; and also that the bread after it is baked will become extremely dry and _crumbly_ much sooner than bread made with other yeast. Yet this bread, when a day old, is exceedingly light and beautiful: albeit some dislike the animal smell and taste which it derives from the milk.

In all these preparations of yeast and dough, it should ever be recollected that "the process of fermentation cannot go on when the temperature is below 30° F., that it proceeds quite slowly at 50°, moderately at 60°, rapidly at 70°, and very rapidly at 80°."

If, therefore, it is desired to have the yeast or dough stand several hours before it is used or baked, it should be kept at a temperature of about 50°. But in the ordinary way of making bread, a temperature varying from 60° to 70°, or about summer heat, is perhaps as near right as it can well be made.

Prof. Thomson gives the following directions for making yeast in large quantities:—"Add ten pounds of flour to two gallons of boiling water;—stir it well into a paste, let this mixture stand for seven hours, and then add about a quart of good yeast. In about six or eight hours, this mixture, if kept in a warm place, will have fermented and produced as much yeast as will make 120 quartern loaves" (of 4 lbs. each.)

A much smaller quantity can be made by observing due proportions of the ingredients.

To raise bread in a very short time without yeast, Prof. Thomson gives the following recipe:

"Dissolve in water 2 ounces, 5 drams and 45 grains of common crystallized carbonate of soda, and mix the solution well with your dough, and then add 7 ounces, 2 drams and 22 grains of muriatic acid of the specific gravity of 1,121, and knead it as rapidly as possible with your dough;—it will rise immediately—fully as much, if not more than dough mixed with yeast—and when baked, will be a very light and excellent bread." Smaller quantities would be required for small batches of bread.

A tea-spoonful or more (according to the quantity of dough or batter) of super-carbonate of soda dissolved in water, and flour stirred in till it becomes a batter, and then an equal quantity of tartaric acid dissolved and stirred in thoroughly, will in a few minutes make very light batter for griddle or pancakes; or if it be mixed into a thick dough, it will make light bread.

Good lively yeast, however, makes better bread than these alkalies and acids: howbeit these are very convenient in emergencies, when bread or cakes must be prepared in a very short time; or when the yeast has proved inefficient.

We see then that wheat meal consists of certain proportions of starch, gluten, sugar, bran, &c.; and that in making loaf bread, we add yeast or leaven, in order to produce that kind of fermentation peculiar to saccharine matter or sugar, which is called vinous, and by which the gas or air is formed that raises the dough. But the sugar is an incorporate part of every particle of the meal, and is therefore equally diffused throughout the whole mass; and hence if we would make the very best loaf bread, the fermentive principle or yeast must also be equally diffused throughout the whole mass, so that a suitable portion of yeast will be brought to act

at the same time on every particle of saccharine matter in the mass.

But let us endeavor to understand this process of fermentation. To speak in the language of chemistry, sugar is composed of certain proportions of carbon, oxygen and hydrogen. The yeast, acting on the sugar, overcomes those affinities by which these substances are held in the constitutional arrangement of sugar, and the process of decay or decomposition of the sugar takes place, which is called vinous fermentation. By this process of decay, two other forms of matter are produced, of an essentially different nature from each other and from the sugar. One of them is called carbonic acid gas or air, being formed by a chemical combination of certain proportions of carbon and oxygen. The other is known by the name of alcohol, and consists of a chemical combination of certain proportions of carbon, oxygen, and hydrogen. Carbonic acid gas is also produced by animal respiration or breathing, by the combustion of wood, coal, &c. &c. and in other ways of nature and of art: but neither in nature nor in art is there any known way by which alcohol can be produced, except by that process of the decay or destruction of sugar called vinous fermentation.

The carbonic acid gas, produced in the manner I have stated, is the air which inflates or puffs up and swells out the bread, when there is sufficient gluten or other cohesive matter in the dough to prevent its escape.

If the dough be permitted to stand too long in a warm place, the fermentation, having destroyed most or all of the sugar, will begin to act on the starch and mucilage, and destroy their nature, and produce vinegar; and therefore this stage of it is called the acetous fermentation: and if it still be permitted to go on, it will next commence its work of destruction on the gluten; and this is called the putrefactive fermentation, because it in many respects resembles the putrefaction of animal matter.

The vinous fermentation, therefore, by which the dough is raised and made light, may be carried to all necessary extent, and still be limited in its action to the saccharine matter or sugar—leaving the starch and gluten, and other properties of the meal, uninjured; and this is the point at which the fermentation should be arrested by the heat that bakes the dough. If it be permitted to go beyond the sugar, and act on the mucilage and starch, and produce acidity, the excellence of the bread is in some degree irreparably destroyed. The acid may be neutralized by pearlash or soda, so that the bread shall not be sour; but still, something of the natural flavor of the bread is gone, and it is not possible by any earthly means to restore it; and this injury will always be in proportion to the extent to which the process of the acetous fermentation is permitted to go in destroying the nature of the starch, and the bread will be proportionably destitute of that natural sweetness and delicious richness essential to good bread. Yet it is almost universally true, both in public and domestic bread-making, that the acetous fermentation is allowed to take place; and saleratus, or soda, or some other chemical agent is employed to neutralize the acid. By this means we may have bread free from acidity, it is true, but it is also destitute of the best and most delicious properties of good bread; and generally, by the time it is twenty-four hours old—and this is particularly true of bakers' bread—it is as dry and tasteless and unsavory as if it were made of plaster of Paris.

Many bread-makers mix their saleratus or soda with their yeast, or introduce it when they mix their dough, so that if the acetous fermentation does take place, the acid is neutralized by the alkali, and therefore, not being perceived, it is supposed never to have existed, and the bread is called sweet and good; especially if a small quantity of molasses be employed in making the dough. Others far more wisely withhold their alkali till the dough is raised enough to mould into the loaf, and then if it is found to be in any degree acid, a solution of saleratus or soda is worked into it, so as just to neutralize the acid, and no more. This is infinitely better that no have sour bread, which, after all, is almost everywhere met with; yet the very best bread that can be made in this way is only second best. Happy are they who can make good light and sweet bread, without the use of molasses—without suffering the least degree of acetous fermentation to take place, and without employing saleratus, soda, or any other kind of alkali.

The third or putrefactive stage of fermentation rarely takes place in domestic bread-making; but it is by no means uncommon in public bakeries. Indeed it is thought necessary in the manufacture of certain kinds of crackers, in order to make them split open, and render them brittle, and cause them readily to become soft when dipped into water. But dyspepsia crackers, and all other kinds of bread made in this way are, to say the least of them, miserable stuff. For besides the fact that all the best qualities of the flour or meal have been destroyed by fermentation, the great quantity of alkali employed in neutralizing the acid, is necessarily injurious to the digestive organs.

PREPARATION OF BREAD.

Mixing. Much kneading necessary. Rising, or fermentation. Use of alkalies, saleratus and soda. Baking. Ovens. Alcohol in bread. Preservation of bread.

Now, then, the business of the bread-maker is, to take the wheat meal, prepared in the manner I have stated, and with all the properties I have described, and convert it into good, light, sweet, well-baked bread, with the least possible change in those properties; so that the bread, when done, will present to the senses of smell and taste, all the delicious flavor and delicate sweetness which pure organs perceive in the meal of good new wheat, just taken from the ear and ground, or chewed without grinding; and it should be so baked that it will, as a general statement, require and secure a full exercise of the teeth in mastication.

In order to do this, as we have seen, it is necessary, in the first place, that the wheat should be of the best kind, and well cleansed, and the meal properly prepared. In the next place, it is necessary that the yeast should be fresh, lively and sweet; and in the third place, it is necessary that the dough should be properly mixed, raised and baked.

Take then such a quantity of meal, in a perfectly clean and sweet bread trough, as is necessary for the quantity of bread desired, and having made a hollow in the centre, turn in as much yeast as a judgment matured by sound experience shall deem requisite; then add such a quantity of water, milk and water, or clear milk, as is necessary to form the meal into a dough of proper consistency. Some prefer bread mixed with water alone; others prefer that which is mixed with milk and water; and others think that bread mixed with good milk is much richer and better; while others dislike the animal odor and taste of bread mixed with milk. Perhaps the very best and most wholesome bread is that which is mixed with pure soft water, when such bread is made perfect. But whether water, milk and water, or milk alone is employed, it should be used at a temperature of about blood heat.

Here let it be understood, that the starch of the meal is of such a nature that, by a delicate process peculiar to itself, it becomes changed into sugar or saccharine matter; and when the fluid used in mixing the dough is of a proper temperature, and the dough is properly mixed and kneaded, this process, to some small extent, takes place, and a small portion of the starch is actually converted into sugar, and thereby increases the sweetness of the bread. Let it also be recollected here, that the saccharine matter on which the yeast is to act, is equally diffused throughout the whole mass of the meal; and therefore if the yeast be not properly diffused throughout the whole mass, but is unequally distributed, so that an undue quantity of it remains in one part, while other parts receive little or none, then the fermentation will go on very rapidly in some parts of the mass, and soon run into the acetous state, while in other parts it will proceed very slowly or not at all; and consequently large cavities will be formed in some parts of the dough, while other parts of it will remain as compact and heavy as when first mixed, and sometimes even more so. I need not say that such dough cannot be made into good bread; yet it is probably true, that more than nine tenths of the bread consumed in this country is more or less of this character. Nor, after what I have said, should it seem necessary for me to remark, that good bread cannot be made by merely stirring the meal, and yeast, and water or milk together into a thin dough or sponge, and suffering it to ferment with little or no working or kneading. Bread made in this manner, if it is not full of cavities large enough for a mouse to burrow in, surrounded by parts as solid as lead, is almost invariably full of cells of the size of large peas and grapes; and the substance of the bread has a shining, glutinous appearance; and if the bread is not sour, it is because pearlash or some other kind of alkali has been used to destroy the acid.

The very appearance of such bread is forbidding, and shows, at a glance, that it has not been properly mixed—that the yeast has acted unequally on different portions of the meal, and that the fermentation has not been of the right kind.

But if the yeast be so diffused throughout the whole mass, as that a suitable portion of it will act on each and every particle of the saccharine matter at the same time, and if the dough be of such a consistency and temperature as not to admit of too rapid a fermentation, then each minute portion of saccharine matter throughout the whole mass will, in the process of fermentation, produce its little volume of air, which will form its little cell, about the size of a pin’s head, and smaller; and this will take place so nearly at the same time, in every part of the dough, that the whole will be raised and made as light as a sponge, before the acetous fermentation takes place in any part. And then if it be properly moulded and baked, it will make the most beautiful and delicious bread—perfectly light and sweet, without the use of any alkali, and with all the gluten and nearly all the starch of the meal remaining unchanged by fermentation.

Proper materials, proper care, a due amount of labor, a suitable length of time, and proper temperature, are all, therefore, necessary to the making of good bread.

With your meal, and yeast, and water or milk brought together before you, then, proceed in the light of the instruction you have now received, to mix your dough; and remember that the more thoroughly you knead it, the more equally you diffuse the yeast throughout the whole mass, and bring it to act on every particle of the saccharine matter at the same time, and the whiter, lighter, and more delicious you make your bread.

Who that can look back thirty or forty years to those blessed days of New England's prosperity and happiness, when our good mothers used to make the family bread, but can well remember how long and how patiently those excellent matrons stood over their bread troughs, kneading and moulding their dough? and who with such recollections cannot also well remember the delicious bread that these mothers used invariably to set before them? There was a natural sweetness and richness in it which made it always desirable; and which we cannot now vividly recollect, without feeling a strong desire to partake again of such bread as our mothers made for us in the days of our childhood.

Let it be borne in mind, then, that without a very thorough kneading of the dough, there can be no just ground of confidence that the bread will be good. "It should be kneaded," says one of much experience in this matter, "till it becomes flaky." Indeed I am confident that our loaf bread would be greatly improved in all its qualities, if the dough were for a considerable time subjected to the operations of the machine which the bakers call the break, used in making crackers and sea-bread.

The wheat meal, and especially if it is ground coarsely, swells considerably in the dough, and therefore the dough should not, at first, be made quite so stiff, as that made of superfine flour; and when it is raised, if it is found too soft to mould well, let a little more meal be added.

When the dough has been properly mixed and thoroughly kneaded, cover it over with a clean napkin or towel, and a light woollen blanket kept for the purpose, and place the bread trough where the temperature will be kept at about 60° F., or about summer heat, and there let it remain till the dough becomes light. But as it is impossible to regulate the quantity and quality of your yeast, the moisture and temperature of your dough, and several other conditions and circumstances, so as to secure at all times precisely the same results in the same time, it is therefore necessary that careful attention should be given that the proper moment should be seized to work over and mould the dough into the loaf, and get it into the oven, just at the time when it is as light as it can be made by the vinous fermentation, and before the acetous fermentation commences.

If, however, by any means there should unfortunately be a little acidity in the dough, take a small quantity of saleratus, or, what is better, carbonate of soda, and dissolve it in some warm water, and carefully work in just enough to neutralize the acid. The best bread-makers are so exceedingly careful on this point, that they dip their fingers into the solution of saleratus or soda, and thrust them into the dough in every part, as they work it over, so as to be sure that they get in just enough to neutralize the acid, and not a particle more.

I must here repeat, that they who would have the very best of bread, must always consider it a cause of regret, that there should be any necessity to use alkali; because the acetous fermentation cannot in any degree take place, without commensurately and irremediably impairing the quality of the bread. And here it should be remarked, that dough made of wheat meal will take on the acetous fermentation, or become sour, sooner than that made of fine flour. This is probably owing principally to the mucilage contained in the bran, which runs into the acetous fermentation sooner than starch.

While the dough is rising, preparations should be made for baking it. Some bake their bread in a brick oven, some in a stove, some in a reflector, and some in a baking kettle. In all these ways very good bread may be baked; but the baking kettle is decidedly the most objectionable. Probably there is no better and more certain way of baking bread well than in the use of the brick oven. Good bread-makers, accustomed to brick ovens, can always manage them with a very great degree of certainty; and as a general fact, bread is sweeter, baked in this way, than in any other. Yet, when it is well baked in tin reflectors, it is certainly very fine; and so it is also when well baked in iron stoves. But the baking of bread requires almost as much care and judgment as any part of the process of bread-making. If the oven is too hot, the bread will burn on the outside before it is done in the centre; if it is too cold, the bread will be heavy, raw and sour. If the heat is much greater from below than from above, the bottom of the loaf will burn before the top is done: or if the heat is much greater from above than from below, the top of the loaf will burn before the bottom is done.

All these points therefore must be carefully attended to; and no small excuse ought to be considered a satisfactory apology for sour, heavy, raw or burnt bread; for it is hardly possible to conceive of an absolute necessity for such results; and the cases are extremely rare in which they are not the offspring of downright and culpable carelessness.

The best bread-makers I have ever known, watch over their bread troughs while their dough is rising, and over their ovens while it is baking, with about as much care and attention as a mother watches over the cradle of her sick child.

Dough made of wheat meal requires a hotter oven than that made of fine flour; and it needs to remain in the oven longer. Indeed, it is a general fault of bread of every description, made in this country, that it is not sufficiently baked. Multitudes eat their bread hot

and smoking from the oven in a half-cooked state; and very few seem to think there is any impropriety in doing so. But they who would have their bread good, not only a few hours after it comes from the oven, but as long as it can be kept, must see that it is thoroughly baked.

I have said that the process of vinous fermentation converts a portion of the saccharine matter of the meal into carbonic acid gas or air, by which means the dough is raised and made light; and that the same process converts a portion of the saccharine matter into alcohol. The alcohol thus generated is mostly if not entirely driven off by the heat of the oven when the dough is baking;—and in modern times, ovens have been so constructed in England, as to serve the double purpose of ovens and stills; so that while the bread is baking, the alcohol is distilled off and condensed, and saved for the various uses of arts and manufacture.

The question has, however, been frequently started, whether a portion of the alcohol thus generated, is not contained in the bread when it comes from the oven.

This question cannot be answered with entire certainty; but there are some facts in relation to it of considerable importance.

It is perfectly certain that if two portions of wheat meal or flour be taken from the same barrel or sack, and one portion be made into unleavened bread, and the other portion be made into the very best fermented or raised bread, and both be eaten as soon as they are baked, the fermented bread will digest with more difficulty, and oppress and disturb the stomach more than the unleavened bread will. Indeed it is well known and very generally understood, that few of the articles which compose the food of man in civic life, are so trying to the human stomach, and so powerful causes of dyspepsia, as fresh-baked raised bread.

It is now well known also that alcohol wholly resists the action of the solvent fluid of the stomach, and is entirely indigestible; and always retards the digestion of those substances which contain it. How far all this may be true of carbonic acid gas, is not yet ascertained; but it is difficult to account for the difference between leavened and unleavened bread, as above stated, without supposing that the alcohol or carbonic acid gas, or both of them, are in some degree concerned in rendering the leavened bread, when newly baked, peculiarly oppressive and injurious to the stomach.

This, be it remembered, is purely a conjecture of my own; and I am not entirely certain that it is correct; but I see no other way of meeting the difficulty.

Be it as it may, however, it is very certain that when the bread has been drawn from the oven, and permitted to stand in a proper place twenty-four hours, either by evaporation or some other means, it becomes perfectly matured, and so changed in character, that it is, if properly made, one of the most wholesome articles entering into the diet of man; and at that age, there is not the slightest reason to believe that a particle of alcohol remains in the bread.

When therefore the bread is thoroughly baked, let it be taken from the oven and placed on a perfectly clean and sweet shelf, in a perfectly clean and well ventilated pantry. Do not, as you value the character of your bread, put it into a pantry where you set away dishes of cold meat, cold potatoes, and other vegetables, and keep your butter, cheese and various other table provisions—in a pantry which perhaps is seldom thoroughly cleansed with hot water and soap, and where the pure air of heaven seldom if ever has a free circulation. The quality of your bread should be of too much importance to allow of such reprehensible carelessness, not to say sluttishness. And if you will have your bread such as every one ought to desire to have it, you must pay the strictest attention to the cleanliness and sweetness of the place where you keep it.

If in baking, the outer crust should become a little too dry and crispy, you can easily remedy this by throwing a clean bread or table cloth over it for a short time when it first comes from the oven; but if this is not necessary, let the bread stand on an airy shelf, till it becomes perfectly cool, and when it is twenty-four hours old, it is fit for use; and if it is in all respects properly made, and properly kept, it will continue to be sweet and delicious bread for two or even three weeks, except perhaps in very hot and sultry weather.

When we have acquired the art of making such bread as I have described, in the very best manner, then have we carried the art of cooking to the very height of perfection; for it is not only true, that there is no other artificially prepared article in human diet of so much importance as bread, but it is also true that there is no other preparation in the whole round of cooking, which requires so much care, and attention, and experience, and skill, and wisdom.

WHO SHOULD MAKE BREAD.

Making bread by rule. Bakers. Domestics. Sour bread. An anecdote. Mrs. Van Winkle. Bad bread need not be made. How cake is made. Bread-making a drudgery. Excellent example of a mother. Eating bad bread. Importance of having good bread.

Who then shall make our bread? For after all that science in its utmost accuracy can do, in ascertaining principles and in laying down rules, there is little certainty that any one, who undertakes to make bread merely by rule, will be anything like uniformly successful. We may make a batch of bread according to certain rules, and it may prove excellent; and then we may make another batch according to the same rules, which may be very poor. For if we follow our rules ever so closely, there may be some slight differences in the quality or condition of the meal or the yeast, or something else, which will materially alter the character of the bread, if we do not exercise a proper care and judgment, and vary our operations according as the particular circumstances of the case may require.

Correct rules are certainly very valuable; but they can only serve as general way-marks, in the art of bread-making. Uniform success can only be secured by the exercise of that mature judgment which is always able to dictate those extemporaneous measures which every exigency and circumstance may require; and such a judgment can only result from a care and attention and experience which are the offspring of that moral sensibility which duly appreciates the importance of the quality of bread, in relation to the happiness and welfare of those that consume it.

But are we to look for such a sensibility in public bakers? Can we expect that they will feel so lively and so strong an interest for our enjoyment and for our physical and intellectual and moral well-being, that they will exercise all that care and attention and patience, and watch with that untiring vigilance and solicitude in all the progress of their operations, which are indispensably necessary in order to secure us the best of bread?

Or can we reasonably expect to find these qualifications in domestics—in those who serve us for hire? Many a female domestic, it is true, can make much better bread than her mistress can. Many a female domestic has an honest and sincere desire to do her duty faithfully; but can she be actuated by those sensibilities and affections which alone can secure that careful attention, that soundness of judgment, that accuracy of operation, without which the best of bread cannot uniformly, if ever, be produced?

No;—it is the wife, the mother only—she who loves her husband and her children as woman ought to love, and who rightly perceives the relations between the dietetic habits and physical and moral condition of her loved ones, and justly appreciates the importance of good bread to their physical and moral welfare—she alone it is, who will be ever inspired by that cordial and unremitting affection and solicitude which will excite the vigilance, secure the attention, and prompt the action requisite to success, and essential to the attainment of that maturity of judgment and skilfulness of operation, which are the indispensable attributes of a perfect bread-maker. And could wives and mothers fully comprehend the importance of good bread in relation to all the bodily and intellectual and moral interests of their husbands and children, and in relation to the domestic and social and civil welfare of mankind, and to their religious prosperity, both for time and eternity, they would estimate the art and duty of bread-making far, very far more highly than they now do. They would then realize that, as no one can feel so deep and delicate an interest for their husbands' and children's happiness as they do, so no one can be so proper a person to prepare for them that portion of their aliment, which requires a degree of care and attention that can only spring from the lively affections and solicitude of a wife and mother.

But it is a common thing to hear women say—"We cannot always have good bread, if we take ever so much pains;—it will sometimes be heavy, and sometimes be sour, and sometimes badly baked, in spite of all our care."

It may be true that such things will sometimes happen, even with the best of care;—but I believe that there is almost infinitely more poor bread than there is any good excuse for. The truth is, the quality of bread is a matter of too little consideration; and therefore too little care is given to the making of it. Moreover, the sense of taste is so easily vitiated, that we can very easily become reconciled to the most offensive gustatory qualities, and even learn to love them; and it is a very common thing to find families so accustomed to sour bread, that they have no perception of its acid quality.

"It is very strange," said a lady to me one day at her dinner table, "that some folks always have sour bread, and never know it." She then went on to name a number of families in the circle of her acquaintance, who, she said, invariably had sour bread upon their tables when she visited them—"and they never," continued she, "seem to have the least consciousness that their bread is not perfectly sweet and good."

Yet this very lady, at the very moment she was thus addressing me, had sour bread upon her own table; and although I had for many months been very frequently at her table, I had never found any but sour bread upon it. Still she was wholly unconscious of the fact.

Difficult however as most women think it is, to have good bread always, yet there are some women who invariably have excellent bread. I have known such women. The wife of Thomans Van Winkle, Esq. of the beautiful valley of Booneton, New Jersey—peace to her ashes!—was deservedly celebrated throughout the whole circle of her acquaintance for her excellent bread. Few ever ate at her hospitable board once that did not desire to enjoy the privilege again. I know not how often it has been my good fortune to sit at her table; but the times have not been few; and though long past, and she who presided there has slept for years in her grave, yet the remembrance of those times and of those hospitalities, awakens in my bosom a deep and fervent sentiment of gratitude while I write.

Never at the table of Mrs. Van Winkle did I eat poor bread;—and of my numerous acquaintances who had sat at her table, I never heard one say he had eaten poor bread there. Her bread was invariably good. Nay, it was of such a quality that it was impossible for any one to eat of it, and not be conscious that he was partaking of bread of extraordinary excellence.

Mrs. Van Winkle, said I to her one day, while I was feasting on her delicious bread, tell me truly, is there either a miracle or mystery in this matter of bread-making, by which you are enabled to have such excellent bread upon your table at all times, while I rarely ever find bread equally good at any other table, and at ninety-nine tables in a hundred, I almost invariably find poor bread? Is it necessarily so? Is it not possible for people by any means to have good bread uniformly?

“There is no necessity for having poor bread at any time, if those who make it will give proper care and attention to their business,” replied Mrs. Van Winkle, confidently. “The truth is,” continued she, “most people attach very little importance to the quality of their bread; and therefore they give little care to the preparation of it. If every woman would see that her flour is sweet and good, that her yeast is fresh and lively, that her bread trough is kept perfectly clean and sweet, that her dough is properly mixed and thoroughly kneaded, and kept at a proper temperature, and at the proper time moulded into the loaf, and put into the oven, which has been properly heated, and there properly baked, then good bread would be as common as poor bread now is. But while there is such perfect carelessness and negligence about the matter, it is not surprising that bread should be generally poor.”

Mrs. Van Winkle was undoubtedly correct. If anything like the care were given to bread-making that its real importance demands, a loaf of poor bread would rarely be met with. Indeed, if the same degree of care were given to bread-making, that is devoted to the making of cakes and pastry, we should far more generally be blessed with good bread.

Who does not know, that as soon as girls are old enough to go into company and to give parties, they begin to notice with great interest the qualities of the different kinds of cake and pastry which they meet with; and whenever they find anything very nice, they are exceedingly curious to learn precisely how it was made. And lest memory should be treacherous, they will carefully write down the exact rules for mixing and cooking it;—“so many pounds of flour, so many pounds of butter, so many pounds of sugar, so many eggs, and spice to your taste—the eggs to be beaten so and so, the whole mixed so and so, and baked so many minutes,” &c. &c. And thus with great care and industry they collect and write down, in a book which they keep for the purpose, all the recipes they can get hold of, for making every kind of cake and pastry used in society. And when they are preparing for company, they rarely if ever order Dinah or any other domestic to make their nice cake. They do not regard it as a menial office, but as a highly genteel employment; and their great desire to have their cake and pastry as good as it can be made, prompts them to undertake the manufacture of it themselves. And during this operation, the scales, the measures, the clock or watch, all are brought into requisition; the Recipe Book is placed upon the table before them, and carefully consulted; and everything is done with the utmost precision, and exactitude, and vigilance. And if the young lady feels any misgiving as to her own judgment, or taste, or experience, she earnestly inquires of Ma, or some one else who she thinks is capable of giving her advice in so important a matter.

If in the midst of this employment some one knocks or rings at the door, and a young gentleman is announced, she is not at all embarrassed, but perhaps hastens to the parlor with her delicate hands covered with dough, and with an air of complacency and self-satisfaction, says—“Good morning, Frank—how do you do? I am just engaged in making some cake—I hope you will excuse me for a few moments.”

All this shows that she regards the quality of her cake as of very great importance, and considers it not only perfectly respectable but highly _genteel_, for a young lady to be employed in making cake. But in regard to bread and bread-making, everything is very different; there is none of this early curiosity to learn how to make good bread. Young ladies do not on every occasion when they

find excellent bread, carefully and minutely inquire how it was made, baked, &c., and write down the recipe;—but when a batch of bread is to be made for the family, they either leave it for Mother or some domestic to make, or go about it themselves as some irksome and disreputable piece of drudgery; and consequently they turn the task off their hands with as much despatch and as little trouble as possible. If all things happen to be as they should be, it is well; if not, they must answer for the present. If the yeast happens to be lively and sweet, very lucky. If otherwise, still it must be used. If the dough rises well and is got into the oven before it becomes sour, very fortunate; if not, why, "nobody can avoid mistakes—and bread will sometimes be poor in spite of the greatest care;"—and if a batch of miserable bread is the result of such an operation, then all that remains to be done is to eat it up as soon as possible, and hope for better the next time.

If Frank or Charles or Edward should call while the young lady is engaged in making bread, she is perhaps quite disconcerted, and would not for the world have him know what she is doing;—she sends word to him, either that she is out, or that she is particularly engaged, and begs he will excuse her;—or if by any means she happens unexpectedly to be caught at her employment, she is greatly embarrassed, and makes the best apology she can for being engaged in such menial services.

As a matter of course, while such are the views and feelings entertained on this subject, and while such is the manner in which this duty is performed, it will ever be a mere accident if good bread is made; and a mere accident if such girls ever become good bread-makers when they are wives and mothers.

But if parents, and especially mothers, could view this matter in its true light, how differently would they educate their children. They would then feel that, grateful as it is to a mother's heart to see her daughters highly refined and elegantly accomplished, and able to "make the instrument discourse most eloquent music," and to transfer living nature, with all its truth and beauty and sublimity, to the canvass, still the art of bread-making, when considered in all its relations and intimate connections with human health, and prosperity, and virtue, and happiness, and with reference to the natural responsibilities and duties of woman, is actually one of the highest and noblest accomplishments that can adorn the female character. And then, too, would they consider it of exceedingly great importance, that their daughters should possess this accomplishment, even though they may never be in circumstances which will require the exercise of it.

Some eight or nine years since, I spent several months in the delightful village of Belvidere, on the banks of the Delaware, in Pennsylvania. While there, I enjoyed for a number of weeks the kind hospitality of S■ S■, Esq., a lawyer, and a gentleman of great moral excellence. Mrs. S. was born and brought up, I believe, in Philadelphia. Her father was a man of wealth, and she was the only daughter, and—almost as a matter of course—was indulged in all that she desired. But there were so many of the elements of a good wife and mother in her natural composition, that as soon as she entered into those interesting and important relations, she began to devote herself to the duties of them with a sincerity and conscientiousness which could not fail of success. Surrounded as she was, with wealth, and every comfort and convenience of life, and all of its luxuries that she desired, still she was industrious in her habits, and vigilantly attentive to all the concerns of her household. She usually kept three female domestics, who, by her kind maternal deportment towards them, were warmly attached to her. She had no difficulty in procuring nor in keeping help, because she always treated them in such a manner that they loved to stay with her; and she took much pains to qualify them for the proper discharge of their duties. They evidently loved her, and were sincerely desirous of performing all their services in such a manner as would be pleasing to her. Yet with all these advantages to justify her leaving such a duty to her domestics, Mrs. S. invariably made the family bread with her own hands. Regularly as the baking day came, she went into her kitchen and took her stand beside the bread trough, and mixed and kneaded the dough, and put it in its proper place for rising, and, in due time, moulded it into the loaf and baked it.

Do you always make your bread, madam? I inquired one day, as she returned from the performance of that task. "Invariably," she replied: "that is a duty I trust no other person to do for me."

But cannot your domestics make good bread? I asked. "I have excellent domestics," answered Mrs. S., "and they can, perhaps, make as good bread as I can; for they have been with me several years, and I have taken pains to learn them how to do my work; and they are exceedingly faithful and affectionate, and are always willing to do all they can to please me; but they cannot feel for my husband and my children as I do, and therefore they cannot feel that interest which I do, in always having such bread as my husband and my children will love and enjoy. Besides, if it were certain their care and vigilance and success in bread-making would be always equal to mine, yet it is wholly uncertain how long they will remain with me. Various circumstances may take place, which may cause them to leave me, and bring me into dependence upon those who know not how to make good bread; and therefore I choose to keep my own hand in. But, apart from all other considerations, there is a pleasure resulting from the performance of this

duty, which richly rewards me for all the labor of it. When my bread is made and brought upon the table, and I see my husband and children eat it and enjoy it, and hear them speak of its excellence, it affords me much satisfaction, and I am glad to know that I have contributed so much to their health and happiness; for, while my bread is so good that they prefer it to anything else upon the table, there is little danger of their indulging, to any injurious extent, in those articles of food which are less favorable to their health."

I need not say that this lady invariably had excellent bread upon her table. But instances of this kind are, I regret to say, extremely rare, even in christian communities; and therefore when such cases are known, they ought to be held up as most noble examples of female virtue, and receive such high commendations as their intrinsic merit deserves, and such as will be calculated to beget in the minds of others an exalted sense of the dignity and importance of such duties, and prompt every wife and mother to the intelligent and affectionate performance of them.

For it should ever be remembered that, though our children, while they depend on us for protection, are also properly the subjects of our government, yet as soon as they are capable of appreciating our authority and our influence, they are, like ourselves, moral agents, and ought, in all respects, to be governed and nurtured as such; and therefore it is not enough that we can give them such bread as we think best for them, and _compel_ them to eat it; but the grand point at which the mother should always aim, in this matter, is, to place before her children such bread as is the very best for them, and at the same time, to make it the most agreeable to them, and thereby make their duty and their enjoyment perfectly coincide.

Let no one therefore say she cannot always have good bread, until she can truly affirm that she has fairly made the experiment; that she has, in view of all its relations and bearings, accurately estimated the importance of the quality of her bread in regard to the welfare of her household, and, with a proper sense of her responsibilities as a wife and mother, has _at all times_ felt that interest and exercised that care and attention which so important a duty demands, and without which it must ever be a mere accident whether her bread is good or bad.

They that will have good bread, not only for a single time, but uniformly, must make the quality of their bread of sufficient importance, in their estimation and feelings, to secure the requisite attention to the means by which alone such an end can be made certain. They must not suffer themselves, through carelessness, to get entirely out of bread unexpectedly, and thus be obliged, without due preparation, to make up a batch of such materials as they may happen to have at hand, and bake it in haste, and hurry it to the table. But they must exercise providence and foresight: they must know, beforehand, when their supply of bread will probably be out, and when they will need to make another batch; and they must see beforehand that measures are taken to secure a proper supply of all the requisite materials—see that they are furnished with good meal or flour; and they must be sure to have the best of yeast or leaven, when they need it—and when the time comes for them to make their bread, if by any means the yeast should not be good, let them throw it away and make good, before they proceed to make their bread; for it is infinitely better that the family should even do without bread one day, and eat roasted potatoes, than that they should eat poor bread three or four days; and if, from any cause, the bread should be poor, it is incomparably better to throw it away, than to set it upon the table, to disgust the whole family with bread, and drive them to make most of their meal on something else.

If a lady can ever find a good excuse for having poor bread, she certainly can find none, except perhaps extreme poverty, for setting her poor bread on the table the second time. Yet, too generally, women seem to think that, as a matter of course, if they, by carelessness or any other means, have been so unlucky as to make a batch of poor bread, their family and friends must share their misfortune, and help them eat it up; and, by this means, many a child has had its health seriously impaired, and its constitution injured, and perhaps its moral character ruined—by being driven, in early life, into pernicious dietetic habits.

It was observed many years ago, by one of the most eminent and extensive practitioners in New England, that, during a practice of medicine for thirty years, he had always remarked that, in those families where the children were most afflicted with worms, he invariably found poor bread; and that, as a general fact, the converse of this was true; that is, in those families where they uniformly had heavy, sour, ill-baked bread, he generally found that the children were afflicted with worms.

A careful and extensive observation for a few years, would convince every intelligent mind that there is a far more intimate relation between the quality of the bread and the moral character of a family, than is generally supposed.

"Keep that man at least ten paces from you, who eats no bread with his dinner," said Lavater, in his "Aphorisms on Man." This notion appears to be purely whimsical at first glance; but Lavater was a shrewd observer, and seldom erred in the moral inferences which he drew from the voluntary habits of mankind; and depend upon it, a serious contemplation of this apparent whim, discloses a deeper philosophy than is at first perceived upon the surface.

Whatever may be the cause which turns our children and ourselves away from the dish of bread, and establishes an habitual disregard for it, the effect, though not perhaps in every individual instance, yet, as a general fact, is certainly, in some degree, unfavorable to the physical, and intellectual, and moral, and religious, and social, and civil and political interests of man.

Of all the artificially prepared articles of food which come upon our table, therefore, bread should be that one which, as a general fact, is uniformly preferred by our children and our household,—that one, the absence of which they would notice soonest, and feel the most,—that one which—however they may enjoy for a time the little varieties set before them—they would be most unwilling to dispense with—and which, if they were driven to the necessity, they would prefer to any other dish, as a single article of subsistence.

To effect this state of things, it is obvious that the quality of the bread must be uniformly excellent; and to secure this, I say again, there must be a judgment, an experience, a skill, a care, a vigilance, which can only spring from the sincere affections of a devoted wife and mother, who accurately perceives and duly appreciates the importance of these things, and, in the lively exercise of a pure and delicate moral sense, feels deeply her responsibilities, and is prompted to the performance of her duties.

Would to God that this were all true of every wife and mother in our country—in the world!—that the true relations, and interests, and responsibilities of life were understood and felt by every human being, and all the duties of life properly and faithfully performed!

VARIETIES OF BREAD.

Rye bread. Indian meal bread. Use of sour milk, or butter-milk. Acids. Family grinding.

I have thus far spoken almost entirely of wheaten bread, because I consider that the most wholesome kind of bread for ordinary use—for “daily bread.” When bread is made of superfine flour, the same general rules should be observed.

Rice, barley, oats, rye, Indian corn, and many other farinaceous products of the vegetable kingdom, may also be manufactured into bread, but none of them will make so good bread as wheat. Good rye, raised on a sandy soil, when cleansed and ground in the manner I have already described, and prepared in all respects according to the rules I have laid down, will make very excellent bread. Rye, coarsely ground, without bolting, and mixed with Indian meal, makes very wholesome bread, when it is well made. Good rye and Indian bread is far more wholesome for common or every-day use, than that made of superfine flour.

There are various ways of preparing Indian meal bread; and when such bread is well made, it is very wholesome—much more so, for every-day use, than superfine flour bread. “In a memoir lately read before the French Academy,” says the Journal of Health, “the author undertook to show that maize (Indian corn) is more conducive to health than any other grain; and, as a proof of this, the fact was adduced that, in one of the departments in which this grain was most abundantly and universally used, the inhabitants were remarkable for their health and vigor.”

One great drawback to the wholesomeness of Indian meal bread, however, is, that it is almost universally eaten hot, and too generally, pretty well oiled with butter, or some other kind of animal fat or oil. But Indian meal bread can be prepared in such a manner as to obviate these difficulties, and render it very wholesome.

Barley and oats may be manufactured into very wholesome bread; but they are little used for such purposes in this country.

Rice, peas, beans, potatoes, &c., may also, by mixing them with a portion of wheat or rye flour, be manufactured into bread; but, as I have already stated, there is no other kind of grain or farinaceous vegetable substance from which so good loaf bread can be made, as good wheat.

In making bread from Indian meal, and other kinds of farinaceous substances containing little or no gluten, yeast or leaven is rarely if ever used to make it light. More generally sour milk or butter-milk and saleratus or soda are used for this purpose; and they who do not well understand the principle upon which these substances make their bread light, often greatly impair their own success by their mismanagement.

It is, perhaps, most common for them to mix their sour milk or butter-milk and saleratus together, and wait till the effervescence is over, before they stir in their meal. But by this means they lose the greater part of the gas or air by which their dough should be made light.

The true way is, to take their sour milk or butter-milk, and stir meal into it till a thin batter is formed, and then dissolve their saleratus or soda, and stir that quickly and thoroughly into the batter, and then hastily add meal till the batter or dough is brought into the consistency desired.

If, instead of sour milk or butter-milk, a solution of muriatic or tartaric acid is used, the bread will be equally light. In this case, the batter should be first made with a solution of saleratus or soda, and then the solution of acid should be stirred in as above described. Batter cakes are made in this manner very light and very promptly. When from any cause batter or dough mixed with yeast fails to rise according to expectations, the thorough mixing in, first the solution of muriatic or tartaric acid, and then the solution of saleratus or soda, will, in a few minutes, make the whole mass very light; but such cakes and bread are not so sweet and savory as those raised with good sweet yeast.

I have said that recently ground meal makes far sweeter and richer bread, than that which has been ground a considerable time; but as it is not convenient for many families to send to a mill as often as they would like to have fresh meal, they are obliged generally to use staler meal or flour than they would choose. Yet every family might easily be furnished with a modern patent hand-mill, constructed after the plan of a coffee mill, with which they could at all times, with great ease, grind their wheat, and rice, and corn, as they want it, for bread and other purposes. With these mills they can grind their stuff as finely or coarsely as they wish, for bread or hominy, and always have it very fresh and sweet.

LIGHT & STEARNS,

PUBLISHERS AND BOOKSELLERS,

1 Cornhill, Facing Washington Street,

BOSTON,

Keep constantly on hand a general assortment of SCHOOL, THEOLOGICAL and MISCELLANEOUS BOOKS, for sale on the most reasonable terms, at wholesale and retail—together with a good assortment of STATIONARY. Among the works published by them, they would ask particular attention to the following:

DR. ALCOTT'S WORKS.

We have made arrangements to publish a regular series of works by DR. ALCOTT, of which these are a part:

THE YOUNG MOTHER,

OR

THE PHYSICAL EDUCATION OF CHILDREN.

Second Edition—Embellished by a Vignette.

BY DR. WM. A. ALCOTT.

The "Young Mother" is designed as an every-day manual for those who are desirous of conducting the physical education of the young—from the very first—on such principles as Physiology and Chemistry indicate. It inculcates the great importance of preventing evil—especially physical evil—by implanting good habits. We believe it to be the only work of a popular character, written by a medical man, on this subject, and that it is, on this account, doubly valuable. It is recommended by the Boston Medical and Surgical Journal, and by the Press generally, as a work which should be possessed by every family. The following remarks by the editor of the Portland Christian Mirror, will give some idea of the manner in which it has been noticed in various parts of the country, though many of the best periodicals have spoken of it in still stronger terms of approbation:

"The subject of this book is of vital interest to the whole human family, and is treated by Dr. Alcott with the most intelligible simplicity. We hope it will find its way into the hands of all who are entrusted with the training and rearing of children; and that its sound views will supplant many of those hurtful maxims and practices which are lamentably prevalent, and that the existing

generation of mankind will be succeeded by a more healthy and a more moral race."

Price 75 cts.—By the dozen, 62 1-2 cts.

THE HOUSE I LIVE IN,

OR

THE HUMAN BODY.

Second Edition—entirely re-written, enlarged and improved.

FOR THE USE OF FAMILIES AND SCHOOLS.

BY DR. ALCOTT.

The great difficulty of making a subject which has hitherto been deemed dry and unintelligible, at once agreeable and interesting to the young mind, has led the author of this volume to describe the human body as a HOUSE.

The work treats, first, on the FRAME—consisting of the bones, muscles, tendons, &c.; secondly, of the COVERING—consisting of the skin, hair, nails, eyes, ears, &c.; and thirdly, of the APARTMENTS and FURNITURE—by which are meant the interior cavities and organs. Nearly every anatomical and physiological term which appears in the work is so used or so explained, as to be at once clearly understood and apprehended. The subject is illustrated by numerous engravings.

The best recommendation of this work is, that it has been universally approved of by the families and schools where it has been introduced, and by all medical men who have examined it. It has also received the entire approbation of the Press, and is selling rapidly.

Prices:—50 cts. single—$5.40 a dozen.

WAYS

OF

LIVING ON SMALL MEANS.

A CHEAP MANUAL ON HEALTH AND ECONOMY.

Fifth Edition—Enlarged and Improved.

BY DR. ALCOTT.

This work was prepared to meet the demand of the present exigency. Thousands of families, in the poorer and middling classes of society, are suffering from their unwise attempts to live in the style of those persons whose means are far greater than their own. The author has endeavored to convince them—in a brief manner—that a very few things only, are really indispensable to physical and even intellectual comfort and happiness—and that both these are within the reach of all, even in times like the present, would they be content to live in a manner at once rational, simple and healthful. It discusses the following subjects:

Estates and Business; Houses and Furniture; Equipage and Servants; Dress; Food and Drink; Medicine and Physicians; Books and Schools; Customs and Habits; Society; and gives several interesting Examples of living on small means.

With the emendations and improvements made in this edition, it is believed the work cannot fail to be regarded by every unprejudiced mind, as one of the most useful manuals of the day. Four editions, of 1000 copies each, were sold in a few weeks.

Prices:—25 cts. single—$2.50 a dozen—$20 a hundred.

Will soon be ready,

THE YOUNG WIFE.

Stereotyped—and Embellished by a beautiful Plate and Vignette.

BY DR. ALCOTT.

This work is based on the principle, that the great business of the wife is Education—the education of herself and her family. It therefore exhibits the duties of a wife, especially to her husband, in a manner at once original and striking. The author presupposes her to have set out in matrimony with christian principles and purposes; and hence proceeds to inculcate what he deems the best methods of applying them in the routine of daily life and conversation. We believe that no one can rise from the perusal of this volume without a higher respect for female character, as well as a higher confidence in the divine wisdom of matrimony.

The price will probably be the same as that of the Young Mother.

LIBRARY OF HEALTH,

AND

TEACHER ON THE HUMAN CONSTITUTION.

Monthly—Price $1 a Year, in advance.

DR. ALCOTT, EDITOR.

This is a Periodical work, originally called the “Moral Reformer and Teacher on the Human Constitution.” It is published in numbers of 32 pages each, in neat book style for binding into a volume, illustrated by engravings, and is now on the third year of its publication. The numbers of the two past years are for sale, bound in two neat volumes.

This work discusses, in a familiar manner, all subjects connected with physical education and self-management. It treats on the connection of LIGHT, AIR, TEMPERATURE, CLEANLINESS, EXERCISE, SLEEP, FOOD, DRINK, CLIMATE, the PASSIONS, AFFECTIONS, &c., with HEALTH, HAPPINESS and LONGEVITY. The editor takes the ground that a proper understanding of the constitutional laws of the human body, and of all its organs and functions, and a strict obedience thereto, are indispensable to the highest perfection and happiness—present and future—of every living human being. He deems this knowledge more and more indispensable in proportion to the progress of civilization and refinement. The work is pledged to support no system nor set of principles, any farther than that system and those principles can be proved to be based on the laws of Physiology, and revealed truth, and on human experience; and consequently its pages are always open to fair and temperate discussion.

The work has recently been warmly approved of by GEORGE COMBE, (author of the “Constitution of Man,”) as well as a large number of distinguished men of this country, among whom are the following:

Dr. John C. Warren, Dr. S. B. Woodward, Rev. Dr. Humphrey, Rev. S. R. Hall, Rev. Hubbard Winslow, Rev. R. Anderson, Rev. Baron Stow, Rev. B. B. Wisner, R. H. Gillet, Esq., Rev. Wm. Hague, Roberts Vaux, Esq., Dr. John M. Keagy, Dr. R. D. Mussey, Prof. E. A. Andrews, Rev. L. F. Clark, Rev. M. M. Carll, Rev. Dr. Fay, Dr. Sylvester Graham.

These recommendations are similar to the following, received from Dr. WARREN:

“The Library of Health, is, in my opinion, an excellent publication. It seems to be well adapted to aid in the great reform in habits and customs which is now going on in this country and Great Britain; and which, it may be hoped, will extend to other parts of the world. I beg leave to recommend this little work to all who are desirous of promoting their health of body and tranquillity of mind.”

Many of the most respectable Journals in the country, have also given their testimony in its favor. The following are a very few of them:

Boston Medical and Surgical Journal, Annals of Education, Abbott’s Religious Magazine, Boston Recorder, Christian Register, Christian Watchman, Zion’s Herald, New York Farmer.

We feel entire confidence in offering this publication to all who are interested in the improvement which Dr. Alcott is endeavoring to promote.

THE YOUNG MAN'S GUIDE.

BY DR. ALCOTT.

We keep a good supply of this work on hand at all times, for sale at wholesale and retail, at the publishers' lowest prices. It is too extensively known to need comment.

DR. GRAHAM'S WORKS.

A LECTURE TO YOUNG MEN,

ON

CHASTITY.

INTENDED ALSO FOR THE SERIOUS CONSIDERATION OF

PARENTS AND GUARDIANS.

Second Edition—Enlarged and Improved, with Notes.

BY DR. SYLVESTER GRAHAM.

The second edition of this important work is nearly double the size of the first, although the price is increased but a trifle. It is selling rapidly. Notwithstanding its value is extensively known, we cannot forbear to insert two or three

TESTIMONIALS.

The following remarks, from the Annals of Education for 1834, are from the pen of WILLIAM C. WOODBRIDGE; whose long and zealous devotion to the cause of education, and whose extensive travels and researches both in Europe and America, and special attention to the subject of which he here speaks, pre-eminently qualify him to judge accurately in the matter:

"We are rejoiced to see a work published in our country, on a topic in physiology which the 'artificial modesty' to which we have formerly alluded, has covered up, until a solitary, but fatal vice is spreading desolation through our _schools_ and _families_, unnoticed or unknown. The experience of teachers, the case-books of physicians, and the painful exposures which accident, or the dreadful diseases which follow in its train, have occasionally produced, have at length forced it upon public attention; and we hope it will not again be forgotten. The work before us is the result of extensive observation and study; its usefulness has been tested by its influence as a lecture; and its views of this evil are in accordance with the experience of the few teachers whom we have known possessed of the moral courage to encounter it. We would offer it to those who have earnestly desired a work on this subject, as one adapted to their purposes. We would recommend its perusal to every _parent_ and _teacher_. We would warn them that those who have been most confident of the safety of their charge, have often been most deceived; and that the youthful bashfulness which seems to shrink from the bare mention of the subject, is _sometimes_ the blush of shame for concealed crime. We feel bound to add, what abundant and decisive evidence has shown, that ignorance on this subject is no protection from the vice—nay, that it is often the original cause or encouragement of it; that it gives tenfold power to the evil example and influence which are so rarely escaped; and that a cure can be effected only by the most careful instruction and long continued discipline, both physical and moral, directed by sad experience, as is presented in this work."

The following brief but highly valuable testimony is from the distinguished superintendent of the Massachusetts Lunatic Hospital at Worcester:

"DEAR SIR:—The subject of your Lecture to Young Men, has been much neglected, although of great importance.

This lecture, while it sounds the alarm to the young, will not fail to awaken the attention of parents, if once perused. It is couched in language as delicate as the nature of the subject will admit, and may be read with propriety and benefit by all.

The evil of which it treats, if I mistake not, is more extensively sapping the foundation of _physical vigor_ and _moral purity_, in the rising generation, than is generally apprehended, even by those who are awake to the danger, and who have witnessed the deplorable influence of it upon its victims.

Yours, with respect,

S. B. WOODWARD."

The following is from Dr. ALCOTT; author of the works advertised on the preceding pages—addressed to Dr. GRAHAM.

"DEAR SIR:—The subject of your Lecture to Young Men is one of immense importance, and demands the profound attention of every friend of man. It is vain longer to shuffle it off, when those whose opportunities best qualify them to give an opinion, do not hesitate to say that solitary vice is rapidly gaining ground among us. It is a subject which must be met.

In this view, I rejoice to find that an increasing demand for your little work has justified the publication of a second edition. I rejoice, especially, to see such sound principles in physiology inculcated and warmly enforced. I have no hesitation in saying that it ought to be circulated throughout our country. It would thus not only save many a young person from the murderous fangs of quackery, but—what is much better—it would prevent the necessity of his applying either to quacks or physicians for relief from a situation in which he ought never to be placed."

The following is an extract from a letter written by the chaplain of one of our New England State Prisons to a brother clergyman in a neighboring state:

"I have read the book _three_ times, and derived more benefit from the last, than from either of the other readings. I like this book. Why is it not in the hands of every young man, especially in cities, to counteract the influence of indecent pictures and corrupting books?

One excellence in Graham's Lecture, as it strikes me, is, that it is so purely philosophical. Even an atheist might see force in his statements. A man must deny many of the best established principles of science, before he can deny most of the conclusions to which the lecturer comes."

The Boston Recorder, and several other valuable periodicals, coincide with these testimonials.

Prices:—62 1-2 cts. single—$6 a dozen—$45 a hundred.

A TREATISE

ON

BREAD AND BREAD-MAKING.

BY DR. GRAHAM.

There has been for some time a considerable demand for this work, and it will doubtless have a wide circulation among all classes of society.

Prices:—37 1-2 cts. single—$4 a dozen—$30 a hundred.

MISCELLANEOUS WORKS.

We would call attention to the following valuable and interesting works, by popular writers:

THE BOSTON BOOK, for 1836 and 1837, being Specimens of Metropolitan Literature. Edited by H. T. TUCKERMAN, and B. B. THATCHER. Elegantly executed, and embellished by Vignettes of the Great Tree and Tri-Mountain.

THE ITALIAN SKETCH BOOK. By H. T. TUCKERMAN. Second edition—revised and enlarged, with a plate.

THE PARENT'S PRESENT. Edited by the author of Peter Parley's Tales. A handsome present for youth; with cuts.

MOGG MEGONE—a Poem, descriptive of New England and its early inhabitants. By JOHN GREENLEAF WHITTIER. Pocket Edition.

BOSTON MECHANIC, and Journal of the Useful Arts and Sciences. The matter furnished by Practical Men. Valuable for mechanics and manufacturers; numerous Cuts.

SCIENTIFIC TRACTS, for the Diffusion of Useful Knowledge. Complete in one volume. By B. B. Thatcher, Dr. Alcott, Dr. C. T. Jackson, Dr. Sylvester Graham, William Ladd, Lieut. R. Park, and others.

THE MORAL REFORMER, and Teacher on the Human Constitution. Edited by Dr. ALCOTT. This work contains a large quantity of matter on Health and Morals, as connected with the education of the Body. With cuts.

REMAINS OF MELVILLE B. COX, (Missionary to Africa,) with a MEMOIR. Published under the superintendence of his brother, GERSHOM F. COX. With a Portrait, and death-bed autograph.

SLAVERY AND THE DOMESTIC SLAVE-TRADE IN THE UNITED STATES. Letters addressed to the American Union for the Relief and Improvement of the Colored Race. By Prof. E. A. ANDREWS.

THE CARPENTER AND HIS FAMILY: ALSO, PRIDE SUBDUED. By the author of the “Black Velvet Bracelet,” &c. An excellent book for youth.

SKETCHES FROM SACRED HISTORY; containing the Story of the Moabitess—the Story of the Queen—and the Story of the Priest. A good book for youth.

MEMOIR OF WILLIAM WILBERFORCE. By THOMAS PRICE. Second American, from the London Edition. With an elegant Portrait, and an Appendix (not in the first edition.)

MEMOIR OF REV. S. OSGOOD WRIGHT, late Missionary to Liberia. By B. B. THATCHER. With a Portrait.

MEMOIR AND POEMS OF PHILLIS WHEATLEY. The Memoir written by a Relative of the Mistress of Phillis. The Poems from the best English Edition. With a Portrait.

SCIENTIFIC & LITERARY JOURNAL

FOR THE

DIFFUSION OF USEFUL KNOWLEDGE.

Semi-Monthly—$2 a Year, in advance.

This work is so well known (it being a continuation of the SCIENTIFIC TRACTS,) that recommendation is unnecessary. The first volume commenced January 1, this year. We believe all who want a scientific work which can be depended upon for its accuracy as well as general value, would be highly gratified with this periodical.

N. B.—The most favorable terms will be offered to those who may wish to purchase any of the preceding works by the quantity, for gratuitous circulation or for any other purpose—and a liberal discount will be made for cash.

FOOTNOTES.

Footnote A:

In this same manner the Sandwich Islanders cooked all their food, when they were first discovered.

Footnote B:

An aged and very respectable member of the Society of Friends, in New York, who had long been extensively engaged in the flour business in that city, and who had always had his family bread made in his own house, was one day asked by his daughter, why he never used the baker's bread:—"Because, my child," replied he, "I know what it is made of."
